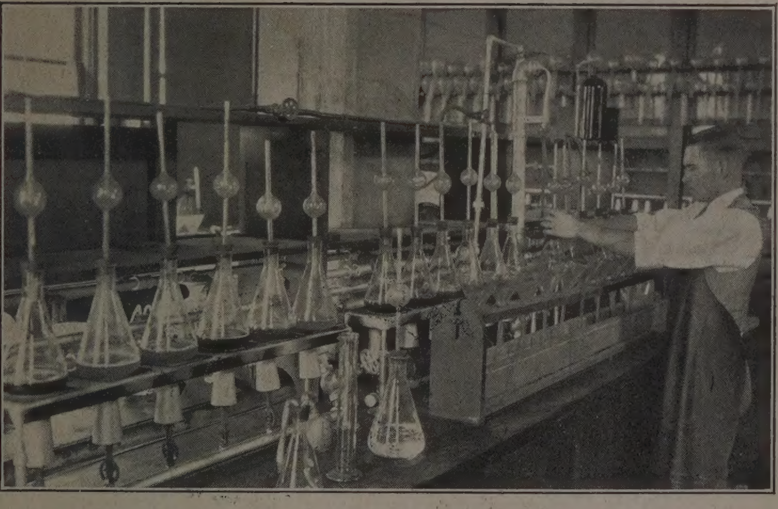
Circular No. 170 March, 1930

ARIZ. UNIV. LIB. 1 5 1930

COMMERCIAL FEEDING STUFFS



It is important to know the amount of crude fiber in commercial feeding stuffs.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular contains a condensed report of Indiana's 1929 commercial feed inspection.

Approximately 498,887 tons of commercial feeds with a retail value of $26,491,777 were sold in Indiana during the year 1929. The inspectors of the State Chemist department secured 2,761 samples, or approximately one sample for each 180 tons of commercial feeds sold in this state.

All of the 2,761 samples collected were examined microscopically and 2,230 were analyzed chemically. It was found that 82 per cent of the samples were equal to or better than the manufacturer's guarantee as declared on the official tag and 486 were not in accord with the official label. Of the 486 samples incorrectly guaranteed, 284 of them would be classed as seriously deficient and sold in violation of the law. Shipments seriously deficient were withdrawn from sale and manufacturers relabeled such feeds correctly and made refunds amounting to $773 to the agents and consumers.

Comments on certain classes of feeding stuffs sold in Indiana during the year 1929.

Summary of the annual tonnage and expenditures for commercial feeding stuffs since 1911.

Explanation of terms used in the analysis of feeds.

The Definitions of Feeding Stuffs adopted by the Association of Feed Control Officials.

Table II gives the average analyses of the common cereals and by-product feeds.

Table III gives the standing of each feed manufacturer on the basis of compliance with the Indiana Feeding Stuffs law both in regard to maintaining guarantees and tagging of his feed. It will pay all purchasers to spend a little time studying this table.

COMMERCIAL FEEDING STUFFS

H. R. Kraybill, State Chemist

O. S. Roberts, P. B. Curtis, C. C. Yund, G. E. Halliday, D. M. Doty

The Indiana Feeding Stuffs law is primarily a correct labeling law. It requires the feeding stuff to be correctly labeled with official labels or tags in order that the prospective buyer may have the information necessary to determine whether the feed is the kind which he wishes to buy. The official tag which bears the facsimile signature of the State Chemist gives the manufacturer's minimum guarantees for crude protein and crude fat and a maximum guarantee for crude fiber. Furthermore the tag states the specific name of each ingredient used in preparing the feeding stuff. Mineral feeds containing no organic ingredient do not require the usual chemical feed guarantee but do require a declaration of each ingredient contained therein and the minimum percentages of lime (CaO), phosphoric acid (P_2O_5), iodine (I) and the maximum percentage of salt ($NaCl$) if same are present. With this information the purchaser is able to distinguish between superior and inferior feeds and to make an intelligent and economical purchase.

In order to verify the correctness of the feed manufacturer's guarantee, the State Chemist collected 2,761 samples of commercial feeding stuffs during the year 1929 from manufacturers, agents and farmers in the various sections of the state. One inspection sample was secured from approximately each 180 tons of commercial feed sold in Indiana. All of the 2,761 samples collected were examined microscopically and 2,230 of them were analyzed chemically. Those not analyzed were largely from shipments previously analyzed. Many of the samples drawn represented carload shipments.

Of the 2,761 samples secured 486 of them were found to be guaranteed incorrectly and 284 were classed as being seriously deficient or misbranded and not sold in accordance with the Indiana Feeding Stuffs law. The year's inspection showed that 82 per cent of the samples were equal to or better than the manufacturer's guarantee, as compared to 77 per cent in 1928.

119952

Refunds and Withdrawals from Sale

Shipments found to be seriously deficient were removed promptly from sale and the manufacturers either replaced the shipment with feed up to the guarantee or else retagged the feed with a correct guarantee. Where deficient feed had already been sold, refunds were made in most cases to the dealers and consumers. During the year 1929 the sum of $773 was refunded on 93 shipments by 63 feed manufacturers. The payment of refunds does not affect the right of any one in the state to call cases of deficiency to the attention of the prosecuting attorney. However, by making these refunds the manufacturer indicates his good intentions and does all that he can to correct the violation of the law.

During 1929 the State Chemist advised the withdrawal from sale of 620.7 tons of commercial feeding stuffs on account of non-tagging, deficiency and misbranding. Of this amount 476.7 tons, representing 170 shipments, were removed from sale on account of non-tagging and 90.1 tons, representing 29 shipments, were removed from sale due to protein deficiency.

Estimated Sales of Commercial Feeding Stuffs in 1929

Approximately 498,887 tons of commercial feeding stuffs with a retail value of $26,491,777 were sold in Indiana in 1929. This estimate was based on the number of tags or labels issued by the State Chemist. Compared with the sales of 1928, the banner year, this shows a decrease of 25,589 tons and a corresponding decrease of $3,326,789 in expenditures. From Table I the principal decreases in tonnage sold during the year 1929 compared with 1928 were for hominy feed, corn feed meal, mill by-products, proprietary feeds and condimental stock feeds while the principal increases were for poultry mashes, linseed oil meal and mineral feeds.

Attention! Manufacturers, Dealers, and Consumers

The official tag required by law bears the facsimile signature of the State Chemist and contains the manufacturer's guarantee.

Dealers and consumers should not accept any shipments without State Chemist tags or with such tags showing alterations. When such shipments are received they should not be accepted until official Indiana labels are furnished. When these are received one should be attached to each bag of 100 pounds or fraction thereof before offering or exposing for sale or selling the feed.

The sale or offering for sale of feed not tagged with official tags constitutes a serious violation of the Indiana Feeding Stuffs law. The law states that a person, company or corporation on conviction of such a violation shall suffer a penalty of $50 for the first offense and $100 for each subsequent offense.

Manufacturers or distributors when shipping feed into this state are especially urged to attach an official Indiana state tag to each bag in the shipment. If this is not done the manufacturer not only violates the law but he also inconveniences his customer who is required to withdraw the feed from sale until it is properly tagged.

Agents and farmers should represent and purchase from manufacturers whose records show that they are complying with the law both in regard to labeling and maintaining guarantees of composition and ingredients. Consult Table III "The Summary of Feed Inspection" and buy from only such companies as have a good record of inspection.

Animal By-Products

Tankage and meat scraps are sold mostly as protein supplements. These products are also valuable in that they furnish mineral constituents, largely tricalcium phosphate ($Ca_3(PO_4)_2$). Analyses of samples found on sale in 1929 show that this class of feeds is often deficient in protein and sometimes adulterated with hoof, horn, hair, etc. If meat scraps contain more than 10% phosphoric acid (P_2O_5) they should be designated as meat and bone scraps. During the past year a few shipments were removed from sale due to the above misbranding. When purchasing tankages the comparative cost per unit of protein should always be considered.

Condimental Poultry and Stock Feeds

These preparations which come under the provisions of the Indiana feeding stuffs law are composed usually of some ordinary feeding stuff or feeding stuff adulterant for a base or carrier together with some cathartic, generally glaubers or epsom salts, and appetizers, such as gentian, fenugreek, ginger, or anise, with small amounts of worm seed, poke root, copperas, sulphur, etc.

In many instances where minerals are present it is often difficult to classify the mixture as a remedy or as a mineral feed. However, the ingredients guaranteed and the high price of these mixtures may be helpful to the purchaser in differentiating between these two types of feeds.

It is very doubtful whether it is advisable to continually dose live stock and poultry with these high priced preparations. The decrease in tonnage sold in 1929 compared to 1928 of 1,280 tons may indicate that the feeder is giving more attention to this class of condimental feeds.

Cottonseed Meal

Cottonseed meal is usually purchased for its protein content. It is used quite extensively in the preparation of balanced dairy rations. Of a great number of samples analyzed the past year only two were found to be seriously deficient in crude protein. This unusually fine record seems to indicate that the manufacturers of cottonseed meal are able to control their products and also take great care in furnishing tags with the correct guarantee.

Mineral Feeds

The primary purpose of mineral feeds is to supplement the mineral deficiency in grain and seeds. These feeds are compounded principally of such materials as superphosphate, rock phosphate, bone meal, bone black, precipitated phosphate, limestone, wood ashes, common salt and sometimes an iodine salt. The mineral ingredients must be stated in their common English term, if any such term exists. Such terms as sodium chloride and calcium carbonate will not be accepted in lieu of the terms common salt and limestone as it is not advisable to confuse the purchasers of these mixtures. Besides the ingredients on the tag particular attention should be given to the percentages of lime (CaO), phosphoric acid (P_2O_5), iodine (I) and salt ($NaCl$) if same are present.

In case these terms are not familiar to all perhaps it would be well to mention that a good grade of limestone will contain 53% CaO, steamed bone meal 34% CaO and 29% P_2O_5, superphosphate 24% CaO and 16% P_2O_5 and potassium iodide 76% iodine.

Poultry Mash

During the year 1929 the estimated tonnage of poultry mash sold in this state was 120,563 tons with a retail value of $7,197,611. This class of feed leads all other classes of feeds in amount sold and has no rival when expenditures are considered. In addition to the above tonnage no doubt a large quantity of poultry mash is home-mixed. Whether the mash is purchased ready-mixed or the individual ingredients are purchased to be home-mixed the official Indiana State tag will give useful information to the buyer.

Proprietary Feeds

There are being sold in this state under various names a wide variety of mixtures composed of screenings and oat hulls on up to ingredients of high feeding quality. This class of ready-mixed feeds consists largely of dairy feeds, calf meals, hog and pig feeds and horse and mule feeds. While many of these feeds are of the highest type others have very little feeding value.

Chicken Chuckle and Chicken Charmer

During the past year inquiries have been made regarding certain feeding stuffs of the following brand names manufactured by the Pico Feed Company, Warsaw, Indiana: Chicken Chuckle and Chicken Charmer. Both of these products are registered with this department under the same guarantee as follows: crude protein not less than 1%, crude fat not less than 1% and ingredients: black strap molasses, corn oil, cocoanut oil, soybean oil, gelatin and corn syrup. Analyses of samples of these products show that they contain not less than 97% black strap molasses. In addition to this they may contain small amounts of other ingredients. The price quoted for Chicken Chuckle is $1.50 per gallon. Black strap molasses can be purchased for from 18 to 20 cents per gallon.

TABLE I. ESTIMATED SALES OF COMMERCIAL FEEDING STUFFS IN INDIANA

Kind of Feed	Estimated Tons			Estimated Retail Values Dollars	
	1927	1928	1929	1928	1929
Alfalfa meal and leaf meal	2,063	2,625	2,657	145,950	129,130
Animal by-products (tankage, meat scrap, etc.)	32,813	25,812	26,094	1,791,353	1,823,971
Brewers, distillers' and yeast dried grains	250	197	63	9,259	2,627
Condimental poultry and stock feeds*	2,781	2,937	1,657	455,235	243,082
Corn bran	31	187	....	6,545	....
Corn feed meal	2,406	5,125	3,875	237,800	158,100
Corn germ meal	375	500	1,125	26,150	57,038
Corn gluten meal and feed	1,938	1,875	813	90,562	39,593
Corn and oats chop and miscellaneous chops	4,844	5,312	4,406	240,102	181,087
Cottonseed meal	10,250	8,532	9,406	481,205	510,746
Dried buttermilk semi-solid, condensed, etc	8,156	5,781	7,063	1,064,282	1,181,640
Hominy meal and hominy feed	28,875	60,750	49,031	2,843,100	2,098,527
Linseed oil meal	8,281	7,281	9,719	436,860	622,016
Mill by-products wheat bran, middlings, rye feeds, etc. with and without screenings	133,594	136,250	120,133	6,076,750	4,697,200
Mineral feeds	7,031	7,312	9,188	666,854	690,938
Oat meal by-products oat shorts, oat hulls, oat middlings, oat groats, etc	250	219	188	7,008	7,990
Poultry scratch feed—with and without grit	55,813	38,593	40,906	2,230,675	2,106,659
Poultry mash	61,594	102,375	120,563	6,562,237	7,197,611
Proprietary feeds ready mixed	76,063	110,719	88,781	6,310,983	4,581,100
Soybean oil meal	188	125	531	6,687	31,010
Miscellaneous—beet pulp, rice bran, processed garbage, kelp, cocoanut oil meal, peanut oil feed, etc	2,938	1,969	2,688	128,969	131,712
Totals	440,534	524,476	498,887	29,818,566	26,491,777

*Not all condimental feeds come under the law.

WITHDRAWALS FROM SALE

Number of shipments withdrawn from sale	Number of manufacturers represented	Reasons for withdrawal from sale	Amount withdrawn tons

Estimated retail value, dollars	20,945,026	16,837,512	24,173,605	29,818,566	26,491,777		

Explanation of Terms Used in the Analysis of Feeding Stuffs

Moisture is the varying quantity of water occurring in feeding stuffs which can be driven off by heat at the temperature of boiling water. The amount of water present varies with the temperature, moisture content of the air, process of manufacture and the character of the substance. In most concentrates this value ranges from five to fifteen per cent.

Crude Fat consists mainly of fats and oils with small amounts of waxes, resins, coloring matter and similar substances, dissolved from feeding stuffs by dry ether. In calculating the heat and energy value of a feed, the fat is considered 2.25 times greater than that of either carbohydrates or protein.

Crude Protein is the term applied to the nitrogenous constituents of a feeding stuff. It is obtained by multiplying the total nitrogen by 6.25. Protein is the most important as well as the most costly constituent in a feed. Plants have the power of building up protein from the inorganic elements of the soil and air while animals must secure their protein from the plants or other animals. The plant proteins contain varying amounts of the essential amino acids, therefore it is necessary to carefully select a variety of feeds which will furnish the essential amino acids economically.

Crude Fiber is the woody portion of a feeding stuff, for the most part cellulose, and is insoluble in dilute acids and alkalis. Most of the common seeds and grains contain very little fiber while the hulls, husks and stems are high in this constituent. In poultry and swine crude fiber when present in considerable quantities exerts a retarding influence on the digestion of nutrients present.

Ash, the mineral matter of plants, is the residue left after burning a feeding stuff at low redness. It consists chiefly of the phosphates, sulphates, chlorides and carbonates of sodium, potassium, calcium and magnesium. The calcium and phosphorous are absolutely essential for the proper nutrition of the animal.

Nitrogen Free Extract consists of sugars, starches, pentoses, non-nitrogenous organic acids, etc., and is determined by subtracting the sum of moisture, crude fat, crude protein, crude fiber and ash from 100.

Carbohydrates is the sum of the crude fiber and Nitrogen-free extract.

DEFINITIONS OF FEEDING STUFFS

Meal is the clean sound ground product of the entire grain, cereal, or seed which it purports to represent.

Chop is a ground or chopped feed composed of one or more different cereals or by-products thereof. If it bears a name descriptive of the kind of cereals, it must be made exclusively of the entire grains of those cereals.

Ear Corn Chops is corn and cob chopped, without the husk, with not a greater proportion of cob than occurs in the ear corn in its natural state.

Head Chops consist of the entire head of the grain sorghums chopped, and should bear the name of the sorghum from which it is made. This includes, among others, kaffir head chops, milo head chops, feterita head chops, and sorghum head chops.

Head Stems consist of the head of the grain sorghums, from which the grain has been removed, and should bear the name of the sorghum from which it is made.

Alfalfa Products

Chopped Alfalfa is the entire alfalfa hay, chopped and not ground finely enough to become a meal. It must not contain an admixture of alfalfa straw or other foreign material.

Alfalfa Meal is the product obtained from the grinding of the entire alfalfa hay, without the addition of any alfalfa stems, alfalfa straw or foreign material, or the abstraction of leaves. It must be reasonably free from other crop plants and weeds, and must not contain more than 33 per cent of crude fiber.

Alfalfa Leaf Meal is the ground product consisting chiefly of leafy materials separated from alfalfa hay. It must be reasonably free from other crop plants and weeds and must not contain more than 18 per cent of crude fiber.

Alfalfa Stem Meal is the ground product remaining after the separation of the leafy material from alfalfa hay or meal. It must be reasonably free from other crop plants and weeds.

Animal By-Products

Blood Meal is ground, dried blood.

Blood Flour is dried blood, prepared by special processes and reduced to a fine powder.

Digester Tankage, Meat Meal Digester Tankage, Meat Meal Tankage, or **Feeding Tankage** is the residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry rendering or a mixture of the products made suitable by drying and grinding. When these products contain more than 10 per cent phosphoric acid (P_2O_5) they shall be designated **Digester Tankage With Bone, Meat and Bone Meal Digester Tankage, Meat and Bone Meal Tankage,** or **Feeding Tankage With Bone.** If they bear a name descriptive of their kind, composition or origin they must correspond thereto.

Meat Scraps is the ground dry-rendered residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice. When this product contains more than 10 per cent phosphoric acid (P_2O_5) it shall be designated **Meat and Bone Scraps.** If they bear a name descriptive of their kind, composition or origin they must correspond thereto.

Raw Bone Meal is the dried, ground product suitable for animal feeding, obtained by cooking in water at atmospheric pressure, undecomposed bone, just enough to remove excess fat and meat. It must not contain less than 23 per cent of protein.

Steamed Bone Meal is the dried, ground product suitable for animal feeding obtained by cooking bones with steam under pressure.

Special Steamed Bone Meal is the dried, ground product suitable for animal feeding obtained by cooking dried bone after the removal of grease and meat fibre with steam under pressure in the process of obtaining gelatine or glue.

Apple Products

Dried Apple Pomace is the sound, dried residue obtained by the removal of cider from apples.

Dried Apple Pectin Pulp is the sound, dried residue obtained by the removal of pectin from apple products.

Barley Products

Barley Hulls are the outer coverings of the barley.

Barley Feed is the entire by-product resulting from the manufacture of pearl barley from clean barley.

Barley Mixed Feed is the entire offal from the milling of barley flour from clean barley and is composed of barley hulls and barley middlings.

Ground Barley is the entire product obtained by grinding clean sound barley, containing not less than 90 per cent pure barley and not more than 10 per cent of other grains, weed seeds and other foreign material and not more than 6 per cent fiber; provided that no portion of this stated 10 per cent of other grains, weed seeds or other foreign material shall be deliberately added.

Mixed Feed Barley is the entire product obtained by grinding country run barley containing not less than 75 per cent pure barley and not more than 25 per cent of other grains, weed seeds and other foreign material; provided that no portion of this stated 25 per cent of other grains, weed seeds or foreign material shall be deliberately added. The ingredients must be stated as barley, other grains, weed seeds and foreign material.

Brewers' and Distillers' Products

Brewers' Dried Grains are the properly dried residue from cereals obtained in the manufacture of beer.

Distillers' Dried Grains are the dried residue from cereals obtained in the manufacture of alcohol and distilled liquors. The products shall bear the designation indicating the cereal predominating.

Distillers' Corn Solubles, a by-product from the manufacture of alcohol from corn, is a mash liquor concentrated after the removal of the alchohol and wet grains.

Distillers' Rye Solubles, a by-product from the manufacture of alcohol from rye, is a mash liquor concentrated after the removal of the alcohol and wet grains.

Distillers' Corn and Rye Solubles, a by-product from the manufacture of alcohol from corn and rye, is a mash liquor concentrated after the removal of the alcohol and wet grains.

Malt Sprouts are the sprouts of the barley grain obtained in the malting process. Sprouts derived from any other malted cereal must be designated by the name of that cereal.

Yeast or Vinegar Dried Grains are the properly dried residue from the mixture of cereals, malt and malt sprouts (sometimes cottonseed meal) obtained in the manufacture of yeast or vinegar, and consists of corn or corn and rye from which most of the starch has been extracted, together with malt added during the manufacturing process to change the starch to sugars, and malt sprouts (sometimes cottonseed meal) added during the manufacturing process to aid in filtering the residue from the wort and serve as a source of food supply for the yeast.

Buckwheat Products

Buckwheat Shorts or **Buckwheat Middlings** are that portion of the buckwheat grain immediately inside of the hull after separation from the flour.

Corn Products

Corn Bran is the outer coating of the corn kernel.

Corn Feed Meal is the by-product obtained in the manufacture of cracked corn, with or without aspiration products added to the siftings. This name is also correctly applied to the by-product obtained in the manufacture of table meal from the whole grain by the non-degerming process.

Grits are the hard, flinty portions of Indian corn containing no bran or germ.

Corn Gluten Meal is that part of commercial shelled corn that remains after the separation of the larger part of the starch, the germ and the bran, by the processes employed in the manufacture of cornstarch and glucose. It may or may not contain corn solubles.

Corn Gluten Feed is that portion of commercial shelled corn that remains after the separation of the larger part of the starch and the germs by the processes employed in the manufacture of cornstarch and glucose. It may or may not contain corn solubles.

Maltose Process Corn Gluten Feed is the dried residue from degermed corn, after removal of starch in the manufacture of malt syrup.

Hominy Feed, Hominy Meal or **Hominy Chop** is the kiln-dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the white corn kernel obtained in the manufacture of hominy, hominy grits, and corn meal by the degerming process.

Yellow Hominy Feed, Yellow Hominy Meal or **Yellow Hominy Chop** is a kiln-dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the yellow corn kernel obtained in the manufacture of yellow hominy grits and yellow corn meal by the degerming process.

Corn Oil Cake consists of the corn germ from which part of the oil has been pressed and is the product obtained in the wet milling process of manufacture of cornstarch, corn syrup, and other corn products.

Corn Oil Meal is ground corn oil cake.

Corn Germ Cake consists of corn germ with other parts of the corn kernel from which part of the oil has been pressed, and is the product obtained in the dry milling process of manufacture of corn meal, corn grits, hominy feed, and other corn products.

Corn Germ Meal is ground corn germ cake.

Cottonseed Products

Cottonseed Meal is a product of the cottonseed only, composed principally of the kernel with such portion of the hull as is necessary in the manufacture of oil; provided that nothing shall be recognized as cottonseed meal that does not conform to the foregoing definition and that does not contain at least 36 per cent of protein. Cottonseed meal shall be graded and classed as follows:

1. **Cottonseed Meal**, Prime Quality. Cottonseed meal, prime quality, must be finely ground, not necessarily bolted, of sweet odor, reasonably bright in color, yellowish, not brown or reddish, free from excessive lint, and shall contain not less than 36 per cent of protein. It shall be designated and sold according to its protein content. Cottonseed meal with 36 per cent of protein shall be termed "36 per cent Protein Cottonseed Meal, Prime Quality," and higher grades similarly designated (as "43 per cent Protein Cottonseed Meal, Prime Quality"), etc.

2. **Cottonseed Meal**, Off Quality. Cottonseed meal not fulfilling the above requirements as to color, odor and texture shall be graded "36 per cent Protein Cottonseed Meal, Off Quality," and higher grades similarly designated.

Cottonseed Feed is a mixture of cottonseed meal and cottonseed hulls, containing less than 36 per cent of protein.

Cold Pressed Cottonseed is the product obtained from the subjection of the whole undecorticated cottonseed to the cold pressure process for the extraction of oil and includes the entire cottonseed less the oil extracted.

Ground Cold Pressed Cottonseed is the product obtained by grinding cold pressed cottonseed.

Fish By-Products

Fish Meal is clean dried ground tissues of undecomposed whole fish and/or fish cuttings with or without the extraction of part of the oil.

Fish Residue Meal is the clean, undecomposed residue from the manufacture of glue from non-oily fish.

Linseed and Flax Products

Linseed Cake or **Meal** is oil cake or meal made from flaxseed; provided that the final product shall contain less than 6 per cent of weed seeds and other foreign materials and; provided further, that no portion of the stated 6 per cent of weed seeds and other foreign materials shall be deliberately added.

Old Process Oil Meal, Old Process Linseed Meal is oil meal as defined or linseed meal as defined produced by crushing, cooking and hydraulic pressure.

New Process Oil Meal, New Process Linseed Meal is oil meal as defined or linseed meal as defined produced by crushing, heating and the use of solvents.

Flax Plant By-Product is that portion of the flax plant remaining after the separation of the seed, the bast fiber and a portion of the shives, and consists of flax shives, flax pods, broken and immature flax seeds, and the cortical tissues of the stem.

Ground Flaxseed or **Flaxseed Meal** is the product obtained by grinding flaxseed which has been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process; provided that the final product shall contain less than 4 per cent of weed seeds and other foreign materials; and provided further, that no portion of the stated 4 per cent of weed seeds and other foreign materials shall be deliberately added.

Unscreened Flaxseed Oil Feed Cake is the product obtained by extraction of part of the oil from unscreened flaxseed by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents. The ingredients shall be stated as partially extracted flaxseed and foreign seeds (wheat, wild buckwheat, pigeon grass, wild mustard, etc.).

Ground Unscreened Flaxseed Oil Feed is the ground unscreened flaxseed oil feed cake.

Screenings Oil Feed is the ground product obtained after extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents from the smaller imperfect grains, weed seeds and other foreign materials, having feeding value, separated in cleaning the grain. The name of the grain from which the screenings are separated shall be prefixed to "screenings oil feed."

Oil Cake

Oil Cake is the product obtained after the extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents, from seeds which have been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process. When used alone the term "Oil Cake" shall be understood to designate linseed cake as defined. When used to cover any other product the name of the seed from which it is obtained shall be prefixed to the words "Oil Cake."

Oil Meal or **Ground Oil Cake** is oil cake ground to a meal.

Oat Products

Oat Groats are the kernels of the oat.

Oat Hulls are the outer coverings of the oat.

Oat Middlings are the floury portions of the oat groat obtained in the milling of rolled oats.

Oat Shorts are the covering of the oat grain lying immediately inside the hull, being a fuzzy material, carrying with it considerable portions of the fine floury part of the groat obtained in the milling of rolled oats.

Clipped Oat By-Product is the by-product obtained in the manufacture of clipped oats. It may contain the light, chaffy material broken from the end of the hulls, empty hulls, light immature oats and dust. It must not contain an excessive amount of oat hulls.

Peanut Products

Peanut Oil Cake is the residue after the extraction of part of the oil by pressure or solvents from peanut kernels.

Peanut Oil Meal is ground peanut oil cake.

Unhulled Peanut Oil Feed is the ground residue obtained after extraction of part of the oil from whole peanuts, and the ingredients shall be designated as **Peanut Meal and Hulls.**

Rice Products

Rice Bran is the pericarp or bran layer of the rice, with only such quantity of hull fragments as is unavoidable in the regular milling of rice.

Rice Hulls are the outer coverings of the rice.

Rice Polish is the finely powdered material obtained in polishing the kernel.

Rice Meal is ground brown rice or ground rice after the hull has been removed.

Ground Rough Rice is ground rice from which the hull has not been removed or ground paddy rice.

Rice Stone Bran is the siftings from the materials secured in removing hulls from rice and contains rice germs, broken rice and some rice hulls.

Rice Huller Bran is a product secured by the huller and comes from brown rice and consists mostly of the bran and germs.

Rye Products

Rye Bran is the coarse outer covering of the rye kernel as separated from the cleaned and scoured rye.

Rye Feed, a by-product obtained in the usual process of the milling of rye flour from cleaned and scoured rye grain, consists principally of the mill-run of the outer covering of the rye grain and the germ with small quantities of flour and aleurone.

Rye Red Dog, a by-product obtained in the usual process of the milling of rye flour, consists principally of aleurone with small quantities of flour and fine bran particles and shall not contain more than 3.5 per cent of fiber.

Rye Low Grade Feed Flour consists principally of dark rye flour and small quantities of aleurone and fine bran particles and shall not contain more than 1.5 per cent crude fiber.

Rye Middlings consists of rye feed and rye red dog combined in the proportions obtained in the usual process of milling rye flour.

Rye Flour Middlings consists of rye feed, rye red dog and pure dark rye flour combined in the proportions obtained in the milling of rye flour and shall not contain more than 5 per cent crude fiber.

Velvet Bean Products

Velvet Bean Meal is ground velvet beans containing only an unavoidable trace of hulls or pods.

Ground Velvet Bean and Pod is the product derived by grinding velvet beans "in the pod." It contains no additional pods or other materials.

Wheat Products

Wheat Bran is the coarse outer covering of the wheat kernel as separated from cleaned and scoured wheat in the usual process of commercial milling.

Hard Spring Wheat Products

Standard Middlings consists mostly of fine particles of bran germ and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and shall not contain more than 9.5 per cent crude fiber.

Flour Middlings shall consist of standard middlings and red dog flour combined in the proportions obtained in the usual process of milling and shall not contain more than 6.0 per cent crude fiber.

Wheat Red Dog, a by-product obtained in the usual commercial process of flour milling, consists principally of aleurone with small quantities of flour and fine bran particles and shall not contain more than 4.0 per cent crude fiber.

Wheat Low Grade Feed Flour, a by-product obtained in the usual commercial process of flour milling, consists principally of flour with small quantities of aleurone and fine bran particles and shall not contain more than 1.5 per cent crude fiber.

Wheat Bran and Standard Middlings consists of the two commodities as defined above, mixed in the proportions obtained in the usual process of commercial milling.

Hard Wheat Mixed Feed (mill-run wheat feed) consists of pure wheat bran and flour middlings combined in the proportions obtained in the usual process of commercial milling. This product shall not contain more than 9.5 per cent crude fiber.

Winter Wheat Products

Brown Shorts (Red Shorts) consists mostly of the fine particles of bran, germ and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and shall not contain more than 7.5 per cent crude fiber.

Gray Shorts (Gray Middlings or Total Shorts) consists of the fine particles of the outer bran, the inner bran or bee-wing bran, the germ and the offal or fibrous materials obtained from the "tail of the mill." This product must be obtained in the usual process of commercial milling and shall not contain more than 6.0 per cent crude fiber.

White Shorts or **White Middlings** consists of a small portion of the fine bran particles and the germ and a large portion of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual process of flour milling and shall not contain more than 3.5 per cent crude fiber.

Wheat Mixed Feed (mill-run wheat feed) consists of pure wheat bran and the gray or total shorts combined in the proportions obtained in the usual process of commercial milling. This product shall not contain more than 8.5 per cent crude fiber.

Screenings consists of the smaller imperfect grains, weed seeds, and other foreign materials, having feeding value, separated in cleaning the grain.

Scourings consists of such portions of the cuticle, brush, white caps, dust, smut and other materials as are separated from the grain in the usual commercial process of scouring.

(NOTE) If to any of the wheat or rye by-product feeds there should be added screenings or scourings—as above defined, either ground or unground, bolted or unbolted, such brand shall be so registered, labeled and sold as clearly to indicate this fact. The word "Screenings" or "Scourings," as the case may be, shall appear as a part of the name or brand and shall be printed in the same size and face of type as the remainder of the brand name. When the word "Screenings" appears it is not necessary to show also on the labeling the word "Scourings."

Mineral Feeds

Mixed feed containing both feed and more than 5 per cent of mineral ingredients requires, in addition to the usual declaration of the chemical feed analysis, a declaration of each ingredient contained therein and the minimum percentages of lime (CaO), phosphoric acid (P_2O_5), iodine (I), and the maximum percentage of salt (NaCl) if same is added. If minerals predominate in the mixture, the usual declaration of the chemical feed analysis, with the exception of protein, may be omitted.

Mineral feeds containing no organic ingredient do not require the usual chemical feed guarantee, but do require a declaration of each ingredient contained therein and the minimum percentage of lime (CaO), phosphoric acid (P_2O_5), iodine (I), and the maximum percentage of salt (NaCl) if same are present.

That the mineral ingredients be stated in the common English terms, if any such terms exist.

It being impossible to classify separately the drug ingredients and the mineral ingredients, be it resolved:

(1) That all mixtures containing mineral ingredients generally regarded as dietary factors essential for the normal nutrition of animals and which are sold or represented for the primary purpose of supplying these minerals as additions to rations in which these same mineral factors may be deficient, be classified as mineral feeds.

(2) That all other preparations which are sold or represented primarily for the cure, mitigation or prevention of disease be classified by this association as drugs, medicines or specifics.

Miscellaneous Products

Dried Beet Pulp is the dried residue from sugar beets which have been cleaned and freed from crowns, leaves and sand, and which have been extracted in the process of manufacturing sugar.

Dried Buttermilk Feed is the product resulting from the removal of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added, excepting such as are necessary and permitted in the manufacture of butter. It contains not more than eight per cent (8.0%) of moisture and not more than thirteen per cent (13.0%) of mineral matter (ash).

Evaporated Buttermilk Feed, Concentrated Buttermilk Feed, Condensed Buttermilk Feed, is the product resulting from the removal of a considerable portion of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added excepting such as are permitted and necessary in the manufacture of butter. It contains not less than 27% of total solids, not less than 2% of butterfat, and not more than .14% ash for each per cent of solids. This definition does not prohibit the use of a distinctive trade name, provided it is followed by one of the names given.

Cocoanut Oil Meal or "Copra Oil Meal" is the ground residue from the extraction of part of the oil from the dried meat of the cocoanut.

Ivory Nut Meal is the ground waste material resulting from the manufacture of buttons and similar articles from the vegetable ivory nut.

Processed Garbage is composed of animal and vegetable waste from garbage collected sufficiently often that harmful decomposition has not set in and is separated from material such as crockery, glass, or similar material. Its odor must not be suggestive of the presence of decomposition and it must contain less than one per cent of glass. None of it shall contain knife-like or needle-like particles, and provided further, that the maximum percentage of glass be stated on the label when present in excess of one-fifth of one per cent.

Palm Kernel Oil Meal is the ground residue from the extraction of part of the oil by pressure or solvents from the kernel of the fruit of Elæis guineënsis or Elæis malanococco.

TENTATIVE DEFINITIONS

Table Scrap Meal is the properly cooked dried and ground residue resulting from freshly collected hotel and house garbage from which all metal, crockery, glass, and other foreign material has been removed except in such traces as may unavoidably occur in good factory practice. The finished product shall not be suggestive of material decomposition in odor. It shall not contain any sharp, needle pointed pieces of glass and shall not contain more than one-fifth of one per cent of finely ground glass or dull particles of glass.

Crab Meal is prepared from the undecomposed waste of the crab industry and contains the shell, viscera and part or all of the flesh. It should contain at least 25 per cent protein.

Shrimp Meal is prepared from the undecomposed waste of the shrimp industry and contains the head, hull and/or the whole shrimp.

Milk Products

Dried Skimmed Milk (Feeding) is the product resulting from the removal of water from clean, sound skimmed milk. It contains not more than 8 per cent moisture.

Condensed Skimmed Milk (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound skimmed milk. It contains not less than 27 per cent total solids.

Condensed Cultured Skimmed Milk (Feeding) is the product resulting from the removal of a considerable portion of water from the clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not less than 27 per cent total solids.

Milk Sugar Feed is the by-product from the manufacture of cheese, containing at least 65 per cent lactose (milk sugar).

TABLE II. AVERAGE ANALYSIS OF CEREALS AND BY-PRODUCTS

Material	Description of	Pounds in one hundred		
		Crude fat	Crude protein	Crude fiber
Alfalfa meal	Entire ground hay	1.5	12.0	30.0
Alfalfa leaf meal	Largely alfalfa leaves	2.5	20.0	18.0
Barley	Whole or ground	1.8	11.0	6.0
Beet pulp	Dried	0.9	8.5	18.0
Blood (dried)	Blood meal	0.5	80.0	none
Bone (raw)	Raw bone	3.0	20.0	1.0
Bone (steamed)	Steamed bone	0.5	10.0	1.0
Brewers' dried grains	From manufacture of beer	6.0	26.0	15.0
Buckwheat	Whole or ground	2.2	10.0	10.0
Buckwheat mixed feed	Entire product from manufacture of buckwheat flour	3.2	12.0	28.0
Buckwheat middlings	Entire product from manufacture of buckwheat flour, except the hulls	7.3	28.8	6.4
Buttermilk (dried)	Dried buttermilk	6.0	30.0	none
Buttermilk (condensed)	Condensed buttermilk	2.0	10.0	none
Cane seed	(Sorghum) removed from head and cleaned	2.5	9.0	2.5
Charcoal	Charcoal	none	none	90.0
Cob meal	Ground corn cob	0.5	2.0	31.0
Corn	Old corn No. 2	4.0	9.0	2.0
Corn and cob meal	Ear corn (old)	3.5	8.0	8.0
Corn bran	Containing little corn germ	2.5	7.0	10.0
Corn mill feed	Corn bran, germ and some meal from manufacture of meal or corn flour	7.4	11.0	4.2
Corn feed meal	Manufacture of cracked corn	3.5	9.0	2.0
Corn germ oil meal	Corn germ with part of the oil removed	8.0	20.0	8.0
Corn gluten feed	Remains after the larger part of starch and germ is removed	2.6	25.0	7.0
Corn gluten meal	From manufacture of corn starch and glucose	1.0	42.0	2.0
Corn screenings	Small and broken grains of corn, small pieces cob, etc., romoved from shelled corn	2.7	8.6	8.6

Copra meal	Dried coconut meats with partial extraction of oil	7.6	21.6	8.6
Cottonseed meal (prime quality)	Sold as 36 per cent protein	7.0	36.0	13.0
Cottonseed meal (prime quality)	Sold as 38.5 per cent protein	7.0	38.5	12.0
Cottonseed meal (prime quality)	Sold as 41 per cent protein	7.0	41.0	10.0
Cottonseed meal (prime quality)	Sold as 43 per cent protein	7.0	43.0	9.0
Cottonseed feed	Below 36 per cent protein	4.0	22.8	22.0
Cottonseed hulls	Contains trace of lint and meal adhering	1.8	4.6	38.0
Cowpea	Seeds, pods removed	1.4	20.8	4.1
Distillers' grain (dried)	From corn or rye	9.0	27.0	12.0
Emmer	Often called spelt	2.0	11.5	10.0
Flaxseed	Whole grain or meal without extraction of oil	33.7	22.6	7.1
Flax plant by-product	Shives, pods, etc	2.1	15.0	31.0
Flaxseed screenings	Small and broken grains, flaxseed, weed seed and other foreign material cleaned from flaxseed	8.0	14.0	14.0
Hominy feed, meal or shop	Manufacture of hominy grits or meal by degerminator process	6.0	11.0	6.0
Kafir corn	Milo	2.5	10.0	2.5
Linseed meal (old process)	Oil extracted by pressure	6.0	34.0	8.0
Unscreened flaxseed oil feed	Flaxseed meal and flaxseed screenings	6.0	30.0	9.0
Malt sprouts	Sprout of the barley grain	1.3	27.9	12.1
Meat scraps	High grade scraps from big packers	8.0	50.0	2.5
Millet	Italian millet seed	3.9	10.3	9.4
Milo	Whole or ground	2.5	10.7	2.5
Molasses	From beets	none	3.0	....
Molasses	Blackstrap from cane	none	3.0	....
Oats	Ground or whole	4.0	11.0	11.0
Oat-clipped by-product	Clippings	2.0	9.0	30.0
Oat-groats	Kernels of oat berry	6.5	15.0	2.0
Oat meal mill by-product	Oat hulls and oat shorts	1.5	6.0	28.0
Oat middlings	Floury portion of oat groat	5.0	15.0	5.0
Peanut oil feed	Peanut meats and peanut hulls	6.0	30.0	25.0
Peanut shells	Whole or finely ground	1.2	5.5	70.9
Rice bran	Cuticle layer beneath hull	12.0	12.0	12.0
Rye	Rye	1.5	11.0	2.0
Rye feed	Rye feed	3.5	16.0	5.0
Soy bean	Seed pods removed	19.0	35.0	5.0
Soy bean oil meal	Ground	6.0	40.0	6.0
Sunflower seed	Whole or ground	19.0	16.0	30.0

TABLE II—Continued

Material	Description of	Pounds in one hundred		
		Crude fat	Crude protein	Crude fiber
Tankage (digester)	60 per cent reinforced with concentrated tank water or dried blood	6.0	60.0	2.0
Velvet bean feed	Velvet beans and pods	4.0	19.0	17.0
Wheat	Whole or ground	1.9	11.9	2.4
Wheat bran (soft	Wheat bran	3.5	14.5	8.0
Wheat bran (hard)	Wheat bran	4.0	16.0	10.0
Wheat middlings	Wheat middlings	3.5	15.5	6.0
Wheat standard middlings	With and without screenings	4.0	16.0	9.5
Wheat red dog flour	Red dog flour	3.5	15.0	4.0
Wheat mixed feed and mill run screenings	Bran, middlings, red dog flour and screenings	3.5	15.0	8.0

TABLE III. Summary of Feed Inspection
January 1, 1929, to January 1, 1930

Name and Address of Manufacturer	Number of samples examined	Number of samples passed	Number of samples not passed	Number of samples not tagged

UNIVERSITY OF ARIZONA LIBRARY

Circular No. 171 May, 1930

COMMERCIAL FERTILIZERS

Clover Hay on Bedford Fertility Plots.
201 Lime Alone
202 Lime and Superphosphate
203 Lime and Superphosphate and Potash

UNIVERSITY OF ARIZONA LIBRARY

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular reports the tonnage of commercial fertilizer sold in Indiana for 1929 as calculated by tag sales and as reported by manufacturers. Table X of this circular gives the standing and individual record of every Manufacturer who sold commercial fertilizer in Indiana from whose goods samples were secured.

Table I of this circular shows the tonnage of the 33 analyses for which there is the most demand, reported both by Manufacturers and as estimated from tag sales. The 2-12-6 as in previous years was still the most popular. Manufacturers reported 81,417 tons sold as compared to 74,850 tons calculated from tag sales.

There were 248,566 tons of high grade mixed fertilizer and only 10,506 tons of low and medium grade mixed fertilizer sold in Indiana last year.

More Nitrogen and Potash, and a slight increase of tons of Available P_2O_5 were sold last year which was the banner year as far as sale of gross tons. However, there was a decrease in pounds per ton of actual plant food as compared to the previous year. The average ton of commercial fertilizer for 1929 would have the following analysis (2.1-10.9-6.3) while that of 1928 would be (1.4-13.8-5.7).

Purchasers of Commercial Fertilizer for Fall 1930 and Spring 1931 should read the paragraphs entitled "**SPECIALS**" on page 5 of this circular.

COMMERCIAL FERTILIZERS

H. R. KRAYBILL, *State Chemist*
O. S. ROBERTS O. W. FORD L. E. HORAT
M. H. THORNTON

Fertilizer records in the State Chemist office date back to 1881, when Indiana's first fertilizer law was enacted. Sales of commercial fertilizer were higher for 1929 than for any year since the law was enacted. It is estimated that 291,193* tons of commercial fertilizer with a retail value of $11,317,868 were sold in Indiana in 1929. Inspectors from the State Chemist department visited every county in the state, both spring and fall. 1,378 official samples were drawn, representing one sample for every 211 tons sold. Of these samples 1,217 were equal to or above the guarantee in value, 155 were within 10% of the value guaranteed and 6 were 10% or more below the guarantee in value. Seven of the 920 samples which contained nitrogen showed inferior nitrogen, one was a dried manure which is an inferior source of nitrogen. This record is a slight improvement over that of past years.

The Indiana Fertilizer Law is designed to furnish the purchaser of fertilizer with a label or tag showing an accurate description of the material offered for sale. With this information it is expected that the purchaser will be able to buy intelligently. It is not the purpose of the law to state what fertilizer he shall or shall not buy.

In order that the law may be effective in accomplishing its purpose it is necessary to have the full co-operation of the manufacturers, dealers, agents, and consumers.

A copy of the full text of the law will be sent to persons making requests for the same to the State Chemist, Purdue University Agricultural Experiment Station, Lafayette, Indiana.

REFUNDS

There is every reason to believe that all fertilizer companies now doing business in Indiana are trying to maintain their fertilizer guarantees. Occasionally the fertilizer fails to meet the guarantee. When this occurs and the manufacturer makes a refund to the purchaser, he does not remove the violation of the law but he does indicate his good intentions and does all that he can then do to correct the matter. The payment of these refunds, however, does not nullify the right of any one in the state to call cases of deficiency of analysis to the attention of the prosecuting attorney.

---

* This figure estimated from tag sales is probably high due to the discarding of tags on account of the change from the ammonia to the nitrogen basis, January, 1929.
See page 18 for tonnage as based on manufacturers reports.

All refunds are required to be distributed to the consumer and receipts for the same must be filed with the State Chemist.

Refunds are figured on raw materials when deficient $1.00 or more per ton as calculated from the wholesale price of the same.

Refunds are figured on mixed fertilizers when one ingredient is deficient to the extent of $1.00 or more per ton regardless of the excess of the other ingredients. Variations from this procedure may be applied in cases of deficiencies in double strength fertilizers.

Refunds amounting to $960.95 were paid by 20 companies on 94 shipments of fertilizer during 1929.

MANUFACTURERS

Any material used for manuring purposes except barnyard manure, marl, lime, wood ashes and plaster, must be registered with the State Chemist and properly tagged with the official state tag or label before it is offered or exposed for sale.

Each package whether one ounce or 200 pounds must have an official label attached before it is offered or exposed for sale. Bulk sales must be accompanied by labels sufficient to cover the total weight of the material. Manufacturers make themselves as well as their agents liable to prosecution when they ship untagged fertilizer to the agents.

The law contains no provision for granting permission to make unlabeled shipments. The manufacturer should use the utmost care to tag all shipments properly and thereby prevent the annoyance, inconvenience and expense to his dealers which arise from the removal of material from sale or from prosecution.

The law requires a minimum guarantee for each element which must be stated on the official label. *Since fertilizers are purchased on the basis of their analysis to meet the particular needs of the consumer an excess of one ingredient will not necessarily compensate for a deficiency in another.*

AGENTS, DEALERS, DISTRIBUTORS

The Indiana Fertilizer Law recognizes only the State Chemist labels bearing the facsimile signature of the State Chemist (see reproduction page 21). Do not accept, offer or expose for sale, sell, deliver, distribute or have in your possession any quantity of any commercial fertilizer which does not have attached to the packages or available for bulk shipments, the State Chemist label for each 200 pounds or fraction.

The State Chemist label is always printed and any alterations thereon constitutes a violation of the law. Therefore do not accept any quantity of fertilizer with State Chemist's labels showing alteration.

Manufacturers and their representatives frequently claim that a deficiency in one ingredient is compensated in value by the excess of another ingredient. Such a claim is illogical since each of the plant foods, nitrogen, potash and available phosphoric acid has a specific function to perform in plant production and cannot replace one another.

It is essential that the particular plant food desired and purchased be secured rather than an equal money value of another plant food if a profitable and an economical use of commercial fertilizer is made. Since local agents are directly responsible for the fertilizer they offer for sale, they should protect themselves by a clause in their contract wherein the manufacturer agrees to assume all responsibility for all fines or refunds in cases where the fertilizer fails to meet the requirements of the law.

CONSUMERS

Refuse to accept any fertilizer that is not what you bought or is not correctly labeled. Be guided by the analysis rather than by the brand name. Consult the inspection reports of this department and purchase from those companies whose record of inspection shows that they are maintaining their guarantees.

SPECIALS

During the past year a few cases of trade misrepresentation have been called to the attention of the State Chemist. Two of these are illustrated below. In both cases it was a question of the forms of P_2O_5 being misrepresented. The various forms of P_2O_5 are set forth and explained on page 8 of this circular.

One case was as follows:

1. John Doe's so-called "2-8-8-2" being represented as a 2-16-2. These are not identical analyses. The first guarantees 8% available and 8% insoluble P_2O_5. The second guarantees 16% available P_2O_5. At present prices the available P_2O_5 in the

first would be worth \$9.60 as against \$19.20 in the second; the insoluble P_2O_5 in the first would be \$3.20 or 1/3 as much as the available P_2O_5. These values are based on a valuation of \$1.20 per unit for available P_2O_5 and \$0.40 per unit for insoluble P_2O_5 which is the same valuation for the total P_2O_5 in raw rock phosphate.

Using a value of \$3.80 per unit for nitrogen and \$1.00 per unit for potash and the same values for P_2O_5 as referred to above the "2-8-8-2" would be worth \$22.40 as compared to \$28.80 for the 2-16-2.

2. Another case in point is the so-called "0-0-24-8" being represented as an 0-24-8. The first guarantees 24% insoluble P_2O_5 or the same form of P_2O_5 as the total P_2O_5 in raw rock phosphate and 8% potash. The second guarantees 24% available P_2O_5 and 8% potash. The value of the phosphate in the first is \$0.40 per unit as compared to \$1.20 per unit in the second. The potash in both cases would have the same value.

By carefully reading the tag this trouble may be eliminated. Our advice is—*Read the tag and satisfy yourself! Don't take some one else's word for it!*

A fair and comparatively simple way to decide which of two different fertilizer analyses is the cheaper may be determined by figuring the value of the ingredients of each according to the same standard.

Applying the above values to a 4-16-4 we would have

4	units of nitrogen	\$15.20
16	units of Available P_2O_5	19.20
4	units of Water Soluble Potash	4.00
	Total	\$38.40

Some interesting comparisons are encountered year by year in going over the records.

In the following table the values referred to above were applied to various analyses and this value then inserted between the high and low retail price as found on the open Indiana Fertilizer Market.

Analysis	Minimum Retail Price	Comparative Value	Maximum Retail Price
2-12- 6	$32.00	$28.00	$47.00
4-24-12	52.00	56.00	67.00
2-16- 8	35.00	34.80	39.00
1- 8- 4	26.00	17.40	28.00
2-12- 2	28.00	24.00	34.00
4-24- 4	53.00	48.00	59.00
2- 8- 2	29.00	19.20	34.00
4-16- 4	40.00	38.40	47.00
2-16- 2	33.00	28.80	35.50
2-8-8-2	36.00	22.40	27.00
0-14- 6	27.00	22.80	32.00
0-28-12	57.00	45.00	65.00
0-12-12	32.00	26.40	34.00
0-24-24	60.00	52.80	65.00
0-10-10	27.00	22.00	33.00
0-20-20	48.00	44.00	57.00

MEANING OF ANALYSIS

As recognized under the Indiana Fertilizer Law there are only three valuable fertilizer elements, nitrogen, phosphorus and potassium. These three elements do not occur in a free state but are always combined as chemical compounds. This facilitates the handling of them as commercial fertilizers. A brief discussion of these, their value and availability as plant food, is given in the following paragraphs.

Nitrogen.

From 1881 until the introduction of nitrogen salts on the market—the principal source of nitrogen was of an organic nature as found in dried blood, bone, tankage and slaughter-house by-products, garbage tankage, cotton seed meal, castor pomace, tobacco stems, manure sweepings and dried peat. The products would show very little water soluble nitrogen. The availability of the insoluble organic nitrogen in the above products would be classed as good with the exception of garbage tankage, manure sweepings, tobacco stems and dried peat.

Where as formerly most of the nitrogen was of organic source, today the reverse is true. Very little bone and bone products are found on the market. These have been diverted into the mixed feed channels. The nitrogen found in more than 80% of the fertilizers on the market in Indiana today is of mineral origin and is largely water soluble.

A few of the sources of the mineral or inorganic forms of nitrogen are as follows: nitrate of soda (natural and synthetic), ammonium sulphate, urea, cal urea, cal nitro and calcium nitrate all of synthetic origin.

Whereas in times past, with a limited organic source of nitrogen, the price has been high per unit, there is every reason to expect a very material reduction in the price of nitrogen per unit with the introduction of the new synthetic products.

Since water soluble forms of nitrogen, especially nitrate of soda and ammonium sulphate, are considered as being readily available for plant growth, we class a fertilizer that has 60% of its guaranteed nitrogen as water soluble as satisfactory.

If less than 60% of its guaranteed nitrogen is water soluble then the availability of the insoluble organic nitrogen is determined by the alkaline permanganate method. In this case if the active water insoluble nitrogen is equal to or greater than the inactive the nitrogen is classed as satisfactory. If less than half of the insoluble nitrogen is active the nitrogen is classed as inferior.

In case the nitrogen is found to be inferior the inactive water insoluble nitrogen appears in heavy type in Table X. Manures and garbage tankages that have not been acidulated show an inferior quality of nitrogen. This is not the fault of the manufacturer. The past year's inspection had seven samples showing an inferior source of nitrogen, of which number, one was a manure. This is noted and set forth in Table X of this Circular.

Phosphoric Acid.

The phosphorus in the fertilizer is linked up as chemical compounds with calcium, iron and aluminum. It may be as mono, di or tri calcium phosphate.

As monocalcium phosphate $CaH_4(PO_4)_2$ it is water soluble and readily available to plants for growth.

As di calcium phosphate ($CaHPO_4$) it is soluble in the soil solution and rendered available to plants for growth.

As tri calcium phosphate ($Ca_3(PO_4)_2$) it is less available to plants and becomes available only slowly in the soil.

The bulk of the fertilizer sold today contains mixtures of large amounts of mono and di calcium phosphate and a slight amount of tri calcium phosphate. This is in contrast to the earlier years when most of the fertilizer used was bone where the phosphorus is present as tri calcium phosphate.

In acidulated goods the phosphorus is sold only on the available P_2O_5 content. This would be the sum of the soluble and reverted P_2O_5.

In bone and rock phosphate the phosphorus is sold only on the total P_2O_5 content. It is only fair to state, however, that about

1/3 of the total P_2O_5 content of bone would show available by the neutral ammonium citrate method while rock phosphate would only show from two to four per cent by the same method.

Potash.

Potash, as the official label states, must be soluble in water, in which form it is considered directly available for plant use.

No difference in crop growth has been noted in American, French or German potash. Muriate of potash (KCl) being the cheapest has largely supplanted other potash salts for general crops.

CHANGE FROM AMMONIA TO NITROGEN BASIS

Through an agreement among the various fertilizer manufacturers the first numeral of the analysis of fertilizers has been changed to represent the per cent of nitrogen contained in the fertilizer rather than the per cent of ammonia as was the case heretofore.

In the past the first numeral of the analysis meant percentage of ammonia, the second percentage of available phosphoric acid and the third percentage of water soluble potash. In other words a 2-12-6 fertilizer contained 2 per cent of ammonia (equivalent to 1.65 per cent of nitrogen), 12 per cent of available phosphoric acid and 6 per cent of water soluble potash. Since January 1, 1929, under the new system a 2-12-6 fertilizer contains 2 per cent of nitrogen (equivalent to 2.42 per cent of ammonia), 12 per cent of available phosphoric acid and 6 per cent of water soluble potash.

STUDY THE STATE TAG TO AVOID CONFUSION

The new system applies to all new registrations and orders placed for tags after January 1, 1929. Usually there is some fertilizer held over from the previous season in the hands of dealers. This fertilizer may be offered for sale this year. Fortunately our Indiana law has required the percentage of nitrogen to be stated on the guaranteed analysis on the state tag. This will avoid confusion on the part of the consumer if he will examine the tag carefully. For instance if the analysis following the brand name is 2-12-6 and the guaranteed analysis shows 1.6 per cent nitrogen the analysis is based on the old system and the 2 in the analysis means percentage of ammonia.

If the percentage of nitrogen in the guaranteed analysis on the state tag is a whole number the tags were issued since January

1, 1929. The first figure of the analysis following the brand name is the percentage of nitrogen.

STATE CHEMIST RULING

In order to establish the new method of stating the nitrogen content on a nitrogen basis and to promote uniformity the State Chemist issued the following ruling effective January 1, 1929: "After January 1, 1929, no applications for registration of mixed fertilizers will be accepted except those that are guaranteed to contain minimum percentages of nitrogen, available phosphoric acid and water soluble potash, stated as whole numbers in the preceding order. Any numerals used on the bag or in advertising matter to describe the analysis of the fertilizers being offered for sale must be so arranged that the first numeral will be the minimum guaranteed percentage of nitrogen, the second numeral the minimum guaranteed percentage of available phosphoric acid and the third numeral the minimum guaranteed percentage of water soluble potash."

MOVE TOWARDS SIMPLIFICATION OF TERMS

This change from the ammonia basis to the nitrogen basis has been adopted by the fertilizer manufacturers for the district number 9 represented by the states, Ohio, Indiana, Illinois, Kentucky, Missouri, Kansas, Iowa, Minnesota, Wisconsin, Michigan, and California. Eventually it is hoped that this method of stating the analysis of a fertilizer will be adopted by the entire country. More and more the fertilizer companies are beginning to realize the advantage of simplicity of bag branding and statement of the analysis of fertilizer. Such moves make for a better and clearer understanding of the meaning of the bag branding and the guaranteed analysis which is of mutual benefit to the farmer and the fertilizer companies.

RULINGS ADOPTED BY A. O. A. C.

FERTILIZER GRADE

The grade of a fertilizer shall represent the minimum guarantee of its plant food expressed in terms of nitrogen, available phosphoric acid, and water-soluble potash.

FERTILIZER FORMULA

The term fertilizer formula shall be interpreted as expressing the quantity and grade of the crude stock materials used in making a fertilizer mixture. For example: 800 pounds of 16 per cent acid phosphate, 800 pounds of 9-20 tankage, and 400 pounds of sulfate of potash-magnesia.

FERTILIZER ANALYSIS

The word analysis, as applied to fertilizers, shall designate the percentage composition of the product expressed in terms of nitrogen or ammonia, phosphoric acid, and potash in their various forms.

BRAND AND BRAND NAME

A brand is a term, design, or trade mark used in connection with one or several grades of fertilizers.

A brand name is a specific designation applied to an individual fertilizer.

INTERPRETATION OF BRAND NAME TO INCLUDE THE ANALYSIS OR GRADE OF FERTILIZER

The committee recommends and urges the practice of including the analysis or grade of fertilizer with the brand name, both by the manufacturer on sacks and in printed literature and by the control official in his reports and publications.

UNIT

A unit of plant food is twenty (20) pounds, or one per cent (1%) of a ton.

MEANING OF TERM "FINELY GROUND"

The term finely ground in the definition of basic phosphate slag shall refer to actual size of particles as determined by the use of standard sieves, as follows: seventy per cent (70%) or more should pass a 100-, and ninety per cent (90%) or more should pass a 50-mesh sieve.

"LIME" AS APPLIED TO FERTILIZERS

The term lime shall not be used in the registration, labeling, or guaranteeing of fertilizers or fertilizing materials unless the lime is in a form to neutralize soil acidity, such as the oxide, hydroxide, or carbonate, or equivalent magnesia compounds.

LEACHED WOOD ASHES

Leached wood ashes are defined as ashes resulting from burning unleached wood, but as having had part of their plant food removed by artificial means or by exposure to rains, snows, or other solvent.

UNLEACHED WOOD ASHES

Unleached wood ashes are ashes that result from burning unleached wood, that had had no part of their plant food removed, and that contain four per cent (4%) or more of water-soluble potash (K_2O).

ASHES FROM LEACHED WOOD

Ashes from leached wood are defined as unleached ashes resulting from burning wood that has been exposed to or digested in water or other liquid solvent, as in the extraction of dyes, so that a part of the plant food has been dissolved and removed.

DRIED PULVERIZED OR SHREDDED MANURES

Dried pulverized or shredded manures shall be only what the name indicates, and not mixtures of manures and other materials.

FORM OF NITROGEN IN CYANAMIDE

The nitrogen in calcium cyanamide shall be considered as being of organic nature.

KAINIT

Kainit is a potash salt containing potassium and sodium chlorides and sometimes sulfate of magnesia with not less than twelve per cent (12%) of potash (K_2O).

MANURE SALTS

Manure salts shall be understood to mean potash salts containing high percentages of chloride and from twenty per cent (20%) to thirty per cent (30%) of potash (K_2O). The term double manure salts should be discontinued.

NITRATE OF POTASH (COMMERCIAL POTASSIUM NITRATE)

Nitrate of potash is a salt containing not less than twelve per cent (12%) of nitrogen and forty-four per cent (44%) of potash (K_2O).

MURIATE OF POTASH (COMMERCIAL POTASSIUM CHLORIDE)

Muriate of potash is a potash salt containing not less than forty-eight per cent (48%) of potash (K_2O) chiefly as chloride.

SULFATE OF POTASH-MAGNESIA

Sulfate of potash-magnesia is a potash salt containing not less than twenty-five per cent (25%) of potash (K_2O), nor less than twenty-five per cent (25%) of sulfate of magnesia, and not more than two and five-tenths per cent (2.5%) of chlorine.

SULFATE OF POTASH (COMMERCIAL POTASSIUM SULFATE)

Sulfate of potash is a potash salt containing not less than forty-eight per cent (48%) of potash (K_2O) chiefly as sulfate, and not more than two and one-half per cent (2.5%) of chlorine.

MAXIMUM AMOUNT OF CHLORINE PERMISSIBLE IN FERTILIZERS IN WHICH THE POTASH IS CLAIMED AS SULFATE

The chlorine in mixed fertilizers in which the potash is claimed as sulfate shall not exceed five-tenths of one per cent (0.5%) more than what is called for in the minimum potash content based on the definition for sulfate of potash as formulated by the committee. Calculate as follows: 0.05 times the percentage of potash found plus 0.5.

DEFINITION OF PRODUCTS SECURED BY HEATING CALCIUM PHOSPHATE WITH ALKALI SALTS CONTAINING POTASH

These products are not potassium phosphate. They may be called non-acid phosphates with potash.

BASIC PHOSPHATE SLAG

Basic phosphate slag is a by-product in the manufacture of steel from phosphatic iron ores. The product shall be finely ground and shall contain no admixture of materials other than what results in the original process of manufacture. It shall contain not less than twelve per cent (12%) of total phosphoric acid (P_2O_5), not less than eighty per cent (80%) of which shall be soluble in two per cent (2%) citric acid solution according to the Wagner method of analysis. Any other phosphate slag not conforming to this definition shall be designated low grade.

DISSOLVED BONE

Dissolved bone is defined as a ground bone or bone meal that has been treated with sulfuric acid.

NITRATE OF SODA (COMMERCIAL SODIUM NITRATE)

Nitrate of soda is commercial sodium nitrate containing not less than fifteen per cent (15%) of nitrogen, chiefly as sodium nitrate.

DRIED BLOOD

Dried blood is the collected blood of slaughtered animals, dried and ground and containing not less than twelve per cent (12%) of nitrogen in organic forms.

GROUND RAW BONE

Ground raw bone is a product resulting from drying and grinding animal bones that have not been previously steamed under pressure.

GROUND STEAMED BONE

Ground steamed bone is a product resulting from grinding animal bones that have been previously steamed under pressure.

TANKAGE

The term tankage (without qualification) shall be restricted to meat and bone tankage derived from the rendered, dried and ground by-products from slaughter of animals, or from carcasses of animals that have died otherwise than by slaughter.

FISH TANKAGE, FISH SCRAP, DRY GROUND FISH, FISH MEAL FERTILIZER GRADE

Fish tankage, fish scrap, dry ground fish, fish meal fertilizer grade is the dried ground product derived from rendered or unrendered fish.

GARBAGE TANKAGE

Garbage tankage is the rendered, dried, and ground product derived from waste household food materials.

HOOF AND HORN MEAL

Hoof and horn meal is a product resulting from the processing, drying, and grinding of hoofs and horns.

SUPERPHOSPHATE

Superphosphate is the product resulting from mixing rock phosphate and sulfuric acid and/or phosphoric acid. The grade should always be used as a prefix to the name.

Example: 16% Superphosphate.

It is recommended that the use of the term "Acid Phosphate" be discontinued.

CRUDE, INERT, OR SLOW-ACTING NITROGENOUS MATERIALS

Crude, inert, or slow-acting nitrogenous materials are unprocessed organic substances relatively high in nitrogen but having a very low value as plant food and showing a low activity by both the alkaline and neutral permanganate methods (below fifty per cent (50%) and eighty per cent (80%) respectively).

ACTIVITY OF WATER-SOLUBLE NITROGEN IN MIXED FERTILIZERS

The alkaline and neutral permanganate methods distinguish between the better and the poorer sources of water-soluble nitrogen, and do not show the percentage availablity of the material. The available nitrogen of any product can be measured only after carefully conducted vegetation experiments.

(a) The methods shall be used on mixed fertilizers containing water-soluble nitrogen amounting to three-tenths of one per cent (0.3%) or more of the weight of the material. In the event of a total nitrogen exceeding the minimum guarantee, accompanied by a low activity of the insoluble nitrogen, the over-run may be taken into consideration in determining the classification of the water-insoluble nitrogen.

(b) The water-insoluble nitrogen in mixed fertilizers showing an activity below fifty per cent (50%) by the alkaline method and also below eighty per cent (80%) by the neutral method shall be classed as inferior. This necessitates the use of both methods before classifying as inferior.

CLASSIFIED FERTILIZER SALES SINCE 1883

Since the Indiana Fertilizer Law was passed in 1881 a tremendous change has taken place in the sale of commercial fertilizer in Indiana.

From 8,000 tons sold in 1883, more than 90% of which was bone, we pass to 291,193 tons sold in 1929, where less than 1% was bone. Thus we pass from an organic source of nitrogen found in bone to a mineral source of nitrogen found in nitrogen salts. The mineral source of nitrogen found in nitrogen salts may be either natural or synthetic. These are for the most part water-soluble forms of nitrogen while the organic source of nitrogen in bone is not water soluble to a very large extent.

During the early years farmers depended on the natural fertility of their farms for potash while today they make applications of potash either in the form of potash salts or in mixed fertilizers. Sales of raw materials such as superphosphates, nitrogen salts and potash salts fluctuate, but the increase of sales of mixed fertilizers in which they are an ingredient largely compensates for these fluctuations.

The first appearance of superphosphates on the Indiana market was noted in the years 1886 and 1887. Mixtures of superphosphate and potash appeared at about the same time. Rock phosphate first appeared on the Indiana market in 1897. Sales of this material have never been high.

Bulletin of 1906 reported that up to that time nitrate of soda, ammonium sulphate, and calcium nitrate were used very little, if at all, in fertilizers sold in this state. The sale of these products was first reported in the 1909 Bulletin. In the year 1918, when the United States was in the World War, the importation of potash salts was reduced and they were almost completely eliminated from the market.

The following table illustrates these facts:

TABLE II. CLASSIFIED FERTILIZER SALES SINCE 1883

Year	Total Tons	Tons Nitrogen Salts	Tons Potash Salts	Tons Super-Phosphate	Tons Bone	Tons Raw Rock Phosphate	Tons Phosphate Potash	Tons Ammoniated Super-Phosphate	Tons Com-Plete
1883........	8,000	....	....	....	8,000	....	....	....	....

* Largely Nitrate of Soda.
† Nitrate of Soda and Ammonium Sulphate.
‡ Light Sales.

WHY THE MULTIPLICITY OF ANALYSES

For the past eight years our records show that about 200 different analyses are being kept alive by manufacturers. This is costly and useless. By following the recommendations of the Purdue University Agricultural Experiment Station (Circular No. 162. Fertilizer for Indiana Soils and Crops) the number of the analyses and the cost of the same could be reduced.

While the analyses listed below are not all recognized recommendations, it shows what might be done by reducing the number and it also shows the uselessness of keeping alive so many registrations.

TABLE I.—Showing tons sold under 33 different analyses for past eight years—calculated from tag sales. A glance at the last two columns shows the difference in tons calculated by tag sales and that reported by Manufacturers as being sold under these 33 analyses for 1929.

ANALYSIS	Year 1922	Year 1923	Year 1924	Year 1925	Year 1926	Year 1927	Year 1928	Year 1929	Rpt. by Mfrs. Year 1929

		3-7-7	115.0	1-13-5	778.6	2-8-8-2	473.4
		3-0-12	1.0	1-12-4	155.2		

D. Bone Products (Steam and Raw Bone—Fertilizer Tankages)—3,477.15.

E. Raw Rock Phosphate—596.8.

F. Miscellaneous—1,164.9.

G. Unclassified (Made up of Superphosphates reported sold in bulk but no definite analysis reported)—63.0.

Summary—

1. Total tons reported—237,590.
2. Tags sales from firms not reporting—12,611.
3. Total tonnage based on reports—250,201 (Items 1 and 2).
4. Total tonnage from tag sales—291,193.

EXPLANATION OF TABLES

Buyers of fertilizer for the Fall of 1930 and the Spring of 1931 should read this circular before buying.

A short study of the column headings will help to a better understanding of the various tables appearing in this circular.

Figures appearing in heavy type indicate the analysis failed to meet the guarantee of the manufacturer. One exception of this rule, namely, heavy type in the third column of Table XI indicates that inferior nitrogen was found in the sample.

The footnotes at the bottom of each page explain whether refund was made, amount of shipment returned to manufacturer, etc.

In case of deficient samples manufacturers were given ten days' advance notice and opportunity to secure a portion of our sample for review of our results by their chemists.

In comparing the standing of the manufacturers, Table X should always be used in connection with Table XI.

The following Table (III) sets forth the total tonnage, retail value, cost per ton, pounds of actual plant food per ton and the cost per pound of plant food for the past 10 years.

TABLE III

Year	Tonnage per year	Retail Value Dollars	Cost per ton Dollars	Pounds per ton actual plant food	Cost per pound Plant Food Cents
1920	231,791	8,637,055	37.26	328	0.114
1921	187,923	6,031,305	32.10	354	0.091
1922	209,310	5,730,536	27.40	372	0.074
1923	198,581	6,293,033	31.70	412	0.077
1924	192,417	6,479,605	33.68	446	0.075
1925	226,148	8,253,670	36.50	458	0.079
1926	228,280	8,464,607	37.22	452	0.082
1927	240,498	8,998,412	37.41	444	0.084
1928	221,082	8,254,591	37.33	444	0.084
1929	291,193	11,327,868	38.89	417	0.094

Year by year the high grade mixed fertilizer is driving low and medium grade mixed fertilizer off the market and this year is no exception as will be seen by inspection of the table below.

The comparison of mixed fertilizer sales for the past ten years follows:

TABLE IV

Mixed Fertilizer	1920 tons	1921 tons	1922 tons	1923 tons	1924 tons	1925 tons	1926 tons	1927 tons	1928 tons	1929 tons
Low and Medium Grade...	84,760	55,887	43,459	25,773	21,759	17,989	16,892	13,722	6,562	10,506
High Grade...	57,881	59,809	89,527	104,990	98,832	127,928	146,177	179,695	179,597	248,566

The following table (V) shows the comparison of tonnage sales for the past nine years with the amount of actual plant food in tons per year with the retail value per year.

TABLE V

Year	Fertilizer tons	Tons of nitrogen, phosphoric acid and potash	Cost Indiana farmers
1920	231,791	37,961.57	$8,637,055.00
1921	187,923	33,170.08	6,031,305.00
1922	209,310	39,026.25	5,730,536.00
1923	198,581	40,929.03	6,293,033.00
1924	192,417	*43,004.72	*6,479,605.00
1925	226,148	51,803.84	8,253,670.00
1926	228,280	51,572.55	8,464,607.00
1927	240,498	53,388.66	8,998,412.00
1928	221,082	49,038.59	8,254,591.00
1929	291,193	60,737.35	11,327,868.00

* Corrected figures for 1924.

A glance at Table VI shows the total nitrogen, potash, available (P_2O_5), Insoluble (P_2O_5), Total (P_2O_5) from bone and Total (P_2O_5) from rock expressed in tons of actual plant food for the past ten years.

TABLE VI.—Plant Food in Tons

Year	Nitrogen	Available phosphoric acid	Insoluble phosphoric acid	Total phosphoric acid (bone)	Total phosphoric acid (rock)	Potash
1920	1,748.56	25,129.73	3,401.61	2,840.77	1,045.18	3,795.72

No. 10500

JOHN DOE & COMPANY,

of Lafayette, Ind.,

Guarantee this

Doe's High Grade Fertilizer

to contain not less than

4.0 per cent. of total nitrogen, (N),
24.0 per cent. of soluble and reverted phosphoric acid, (P_2O_5), and
2.0 per cent. of insoluble phosphoric acid, (P_2O_5).
12.0 per cent. of potash, (K_2O), soluble in water.

H R Kraybill
State Chemist

Purdue University Agricultural
Experiment Station, Lafayette, Ind.

LABELS

The only label recognized under the law is that bearing the facsimile signature of the State Chemist. (See reproduction.) The label as issued is always printed and contains all the facts required by law; any alteration thereon constitutes a violation of the law.

Label No. 10500 guarantees that each 100 pounds of fertilizer will contain at least 4.0 pounds of total nitrogen (N), 24.0 pounds of soluble and reverted phosphoric acid (P_2O_5), and 2.0 pounds of insoluble phosphoric acid (P_2O_5), and 12.0 pounds of water soluble potash (K_2O).

We hope that it will not again be necessary to file affidavits against agents for distributing unlabeled fertilizer. There can be no excuse for shipping unlabeled fertilizer. Agents receiving same should protect themselves by refusing to accept the car. Wire the manufacturer for official labels and write the State Chemist fully concerning the unlabeled shipment.

TABLE VIII.—Fertilizer Tonnage and Estimated Retail Value, 1929

Class of Fertilizer	Spring 1929 tons	Fall 1929 tons	Total 1929 tons	Estimated 1929 Retail Value Dollars
1. Acid phosphate, 14% and less	188	562	750	19,500.00
2. Acid phosphate, 16%	3,106	3,135	6,241	149,784.00
3. Acid phosphate, 18-20%	3,181	9,645	12,826	357,973.66
4. Acid phosphate above 20%	900	938	1,838	92,910.90
*6. Ammonium acid phosphate (medium)	31	31	62	1,929.44
10. Acid phosphate and potash (high)	1,481	2,438	3,919	109,379.29
10a. Acid phosphate and potash above 20 units	27,925	13,156	41,081	1,588,191.46
11. Complete fertilizer (low)	544	719	1,263	42,942.00
12. Complete fertilizer (medium)	6,088	3,093	9,181	259,087.82
13. Conplete fertilizer (high)	36,009	34,282	70,291	2,502,359.60
13a. Complete fertilizer above 20 units	75,194	58,081	133,275	5,737,821.50
14. Steamed bone	400	469	869	40,843.00
15. Raw bone	688	1,093	1,781	81,926.00
16. Tankage	157	31	188	7,608.00
21. Rock phosphate	281	563	844	15,614.00
†22. Nitrogen salts	3,090	50	3,140	194,648.60
†23. Potash salts	1,700	100	1,800	86,994.00
31. Miscellaneous (peat, dried manure, dried blood, garbage, tankage, etc.)	1,594	250	1,844	38,355.20
Total	162,557	128,636	291,193	$11,327,868.47

† Tonnage in these classes estimated on the 200-pound sack or 10 per ton. All other classes estimated on the 125-pound sack or 16 per ton.

* No samples taken. Value based on last year's prices.

PRICES USED IN SECURING COMPARATIVE VALUE OF FERTILIZERS

These values are not for the purpose of fixing the commercial value of mixed fertilizers, but are for comparative purposes only. They are for use in comparing the value of inspection samples with manufacturers' guarantees, and can be used advantageously by fertilizer purchasers in calculating the relative values of various brands offered for sale by different manufacturers.

For use in determining the comparative values of fertilizer inspected in 1930, the following prices have been adopted:

	Per lb. cts.	Per unit or per cent, $
All fertilizers		
Nitrogen (N)	15.0	3.00
Potash (K_2O) Soluble in water	5.0	1.00
Soluble and reverted phosphoric acid (P_2O_5)	6.0	1.20
Mixed fertilizers containing nitrogen		
Insoluble phosphoric acid (P_2O_5)	2.0	0.40
Precipitated bone		
Available phosphoric acid (P_2O_5)	6.0	1.20
Insoluble phosphoric acid (P_2O_5)	5.0	1.00
Animal by-products, bone, tankage, etc.		
Total phosphoric acid (P_2O_5)	4.5	0.90
Basic slag		
Total phosphoric acid (P_2O_5)	4.5	0.90
Rock phosphate (floats) and low grade slag		
Total phosphoric acid (P_2O_5)	2.0	0.40
Mixed fertilizer, acid phosphate, etc., containing no nitrogen		
Insoluble phosphoric acid	.0	0.00

TABLE IX.—Summary of Inspection on the Basis of Composition, Guaranteed, Found, and Retail Values

Class of Fertilizer	Number of Samples	Nitrogen (N), average per cent.		Available phosphoric acid (P_2O_5), average per cent.		Insoluble phosphoric acid (P_2O_5), average per cent.		Total phosphoric acid (P_2O_5), average per cent.		Potash (K_2O), soluble in water average per cent.		Comparative value per ton, dollars		Retail price per ton, average, dollars	Comparison, retail price and found comparative value per ton, dollars	Range in retail price per ton, dollars

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic nitrogen was not determined.
Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

[1] Purchased from Bruce Bowen.

[2] Purchased from E. C. Kellenberger.

[3] Purchased from Henry McCormick.

[4] Sold as 0–12–12.

[5] Purchased from Wm. J. Whetsel.

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic nitrogen was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

[22] Not tagged. Labels furnished. Purchased from B. E. Williams.

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic nitrogen was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic nitrogen was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

[189] Sample to manufacturer.

[190] Refund $2.01. Sample received in the spring.

[191] Refund $2.70.

[192] Purchased from Jess Beydler.

[193] Refund $6.00.

[194] Purchased from S. L. Hunt.

[195] Sample to manufacturer.

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic nitrogen was not determined.
Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

[235] Total refund would be less than $1.00.

UNIVERSITY OF ARIZONA LIBRARY

ARIZ UNIV LIB. 15 [illegible]

CIRCULAR No. 172 JUNE, 1930

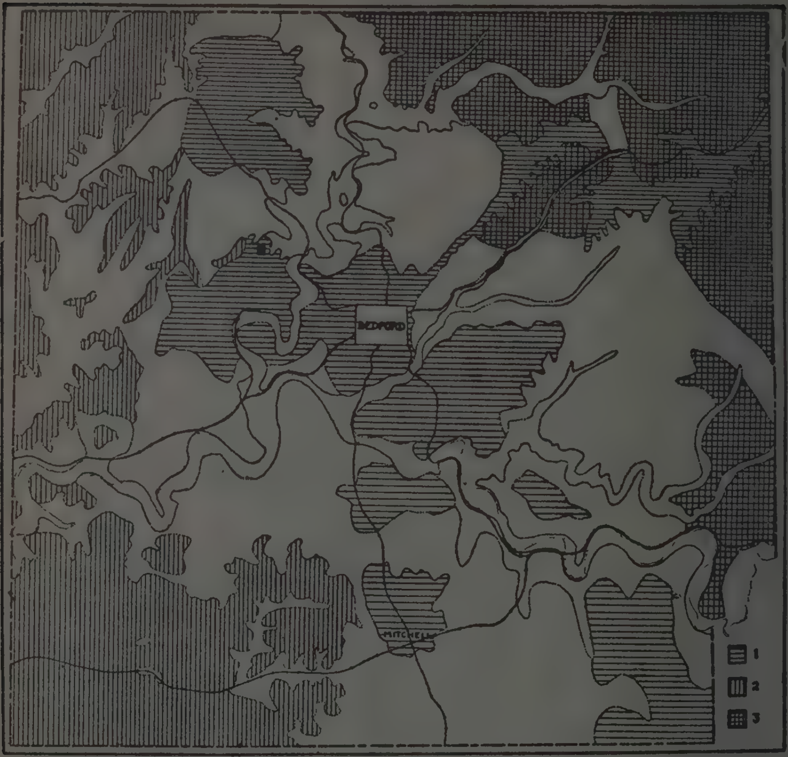
REPORT OF
MOSES FELL ANNEX FARM

Bedford, Indiana

JUNE, 1930

PURDUE UNIVERSITY
Agricultural Experiment Station
Lafayette, Indiana

Map Showing Soil Types Similar to Experiment Field



Region	Principal Soil Characteristics
No. 1.	Yellowish limestone land like Bedford experimental field.
No. 2.	Yellowish "freestone" land.
No. 3.	Like No. 1 on ridge tops and like No. 2 on lower slopes.

The results of the Moses Fell Annex Farm can be applied to the greater part of Lawrence County and surrounding territory.

The soil survey made in this county in 1922 enabled the Department of Agronomy to classify the soils of this section and to indicate the types which can benefit most from the experimental work on this farm.

The results will apply to all similar land in the county, which is indicated by shading No. 1 on the map. They will also apply fully as well to the areas indicated by shading No. 2, and more or less fully to the areas indicated by shading No. 3 where the hilltops are like No. 1 and the lower slopes like No. 2.

Portions of the unshaded area would doubtless respond to similar treatments, but most of it does not need either lime or fertilizer to the same extent as the shaded areas.

REPORT OF MOSES FELL ANNEX FARM
JUNE, 1930

H. J. REED, Farm Director HOBART G. HALL, Superintendent

The development of improved farm practices, the choice of highest producing varieties of grain and the most efficient use of fertilizers for crop production are factors that contribute to profitable farming. Satisfactory and reliable information on these subjects can be obtained only by years of continuous study and experiment in the different sections of the state.

A sincere interest in the advancement of the agriculture of Southern Indiana and a realization of the facts already mentioned prompted the Honorable Moses Fell Dunn to give to the Purdue University Agricultural Experiment Station the Moses Fell Annex farm and certain funds in order that permanent experimental fields might be available to study and solve agricultural problems which confront the farmers owning or operating land of a similar nature. He believed that Southern Indiana was well adapted to the production of high quality fruit which could bring profitable incomes to orchardists. He was also interested in the value of alfalfa as a hay and pasture crop for the development of dairying and live stock production.

MOSES FELL DUNN

The soil on this farm represents a large area in Southern Indiana and the results of the experiments can be applied to thousands of farms.

The farm is being operated for the benefit of the farmers in that section without cost to the taxpayers of the state.

The soil experiments have been under way since 1915 and indicate in a very definite manner that this land, if it is not too broken, can be built up to produce profitable crops.

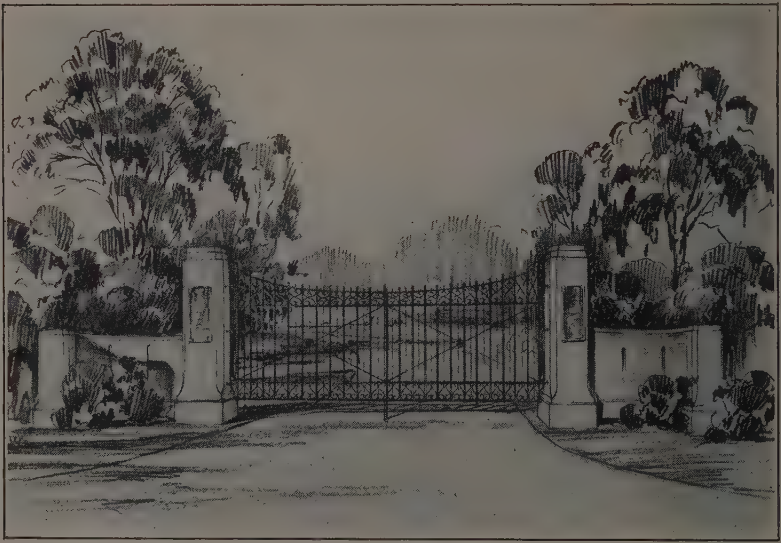
Untreated soil has averaged approximately 21 bushels of corn, 4 bushels of wheat and a half ton of hay. Land receiving lime, manure, and 450 pounds of 16 per cent superphosphate has averaged approximately 53 bushels of corn, 15 bushels of wheat and a ton and a half of hay. An expenditure of $5.04 per acre per rotation for superphosphate has given a return of $36.85 per acre per rotation. The pasture experiments show that the quantity of grass can be greatly increased by proper fertilization. The clover strain test shows very clearly that some strains of red clover seed are not adapted to our use.

Under the direction of the Department of Horticulture, a stationary spray outfit has been installed in about 50 acres of the orchard. Careful records will be kept of the costs of operating this plant. Operating costs of the portable outfit are also being recorded in order that adequate comparisons may be made for fruit growers.

The live stock work has been carried forward as in previous years. A cooperative project with the United States Department of Agriculture has been approved for the study of cattle breeding problems, special attention being given to the establishment of an outstanding herd of dual-purpose Shorthorn cattle.

Satisfactory progress has been made in the development of the purebred flock of Barred Plymouth Rock chickens.

In order to give permanent recognition to Moses Fell Dunn and Antoinette Fell for their worth while and generous service to the agriculture and country life of Southern Indiana, a memorial gateway has been constructed at the entrance of the farm.



The Memorial Gateway.

SOILS AND CROP EXPERIMENTS

When the Moses Fell Annex Farm was taken over in 1914, it did not provide feed and pasture enough for a team of mules which was purchased for farm work. The soil is typical of the upland areas of this section of Indiana—being a yellowish-brown silt loam soil. Under the direction of Professor A. T. Wiancko, chief of the Department of Agronomy, a uniform section of ten acres of poor pasture land was plowed up and planted to corn. The crop produced 23 bushels per acre. This land has been used continuously in fertility tests since, and other land has been added to enlarge the experimental program. The results of soils and crops experiments are reported below by Professor A. T. Wiancko and Professor G. P. Walker.

Effect of manure and phosphate on corn yields, Bedford Experiment Field, 1927. Each shock is the produce of one-twentieth acre. The crop rotation is corn, wheat and clover. Each corn crop received about 6 tons of manure and 450 pounds of 0-16-0 per acre. This treatment has also increased the yields of the other crops by an average of 7.6 bushels of wheat and 1,535 pounds of hay per acre.

Lime alone 18.6 bus. corn per acre	Lime and manure 58.7 bus. corn per acre	Lime, manure and phosphate 74.6 bus. corn per acre

GENERAL SOIL FERTILITY TEST

The soil fertility experiments carried on under the direction of the Agronomy Department are showing more and more striking results.

It will be noted, in comparing earlier reports and in examining the crops on the experiment field, that the spread between the good and poor treatments is becoming greater year by year, and that the better treatments are becoming more and more profitable. Without soil treatment, the average value of the crops per rotation of corn, soybeans, wheat and clover is now $35.63. With lime, manure and phosphate, the value is $94.76, at an average cost of $8.24 for lime and phosphate.

The largest returns have been secured on the limed land, which has received an average of 6.8 tons of manure for corn and 450 pounds of fertilizer divided between the corn and wheat in the rotation of corn, soybeans, wheat and clover. (Plot 20.) The crop increases from this treatment have averaged $59.82 per acre per rotation as compared with the untreated land (plot 14), or a total of $194.41 in thirteeen years. The cost of treatment outside of the manure, which was produced on the farm, has been $10.50 for three tons of ground limestone in 1917 and $4.44 every second year for fertilizer, or a total of $39.36 in the thirteen years.

Phosphorus is by far the most important plant food need of this soil. Applications of superphosphate have been highly profitable, either alone or in addition to manure. Without manure (plot 2) 225 pounds of 16 per cent superphosphate for corn and wheat in the four-year rotation have produced average crop increases of 16.9 bushels of corn, 6.9 bushels of soybeans, 6.8 bushels of wheat and 1,159 pounds of hay per acre, valued at $36.85 for the rotation at a cost of $5.04 for the fertilizer. On land receiving an average of 6.8 tons of manure for corn, a similar use of superphosphate has further increased the crop yields by 10.1 bushels of corn, 5.9 bushels of soybeans, 5.8 bushels of wheat and 1,202 pounds of hay, worth $30.13 at a cost of $5.04 for the phosphate, showing that manure is not sufficient on this land. (Compare plots 16 and 18.)

Manure applied at an average rate of 5.5 tons per acre for the corn has produced average crop increases of 16.7 bushels of corn, 2.5 bushels of soybeans, 2.5 bushels of wheat and 454 pounds of mixed hay per acre, valued at $20.10, which amounts to an average return of $3.64 per ton of manure applied. (Compare plots 14 and 15.)

Ground limestone applied at the rate of three tons per acre in 1917 has so far produced average crop increases of 3.7 bushels of corn, 1.8 bushels of soybeans, 1.7 bushels of wheat, and 521 pounds of mixed hay per acre, valued at $33.34, up to the present time. (Compare plots 13 and 14.)

Lime and manure together have produced average increases of 20.4 bushels of corn, 4.6 bushels of soybeans, 3.9 bushels of wheat, and 775 pounds of mixed hay per acre, amounting to $29.81 for the rotation. (Compare plots 14 and 16.)

Applications of 300 pounds of 0-12-4 on corn and 300 pounds of 4-12-4 fertilizer on the wheat have produced average increases of 19.1 bushels of corn, 6.0 bushels of soybeans, 9.2 bushels of wheat, and 1,108 pounds of mixed hay per acre, amounting to $40.41 at a total cost of $8.88 for the fertilizer. (Compare plots 12 and 14.) The bulk of the increase, however, has been due to the phosphorus in the fertilizer, as is shown in the comparison of plots 2 and 8 with plots 3, 4, 6 and 7.

The field was laid out and tile drained in the spring of 1917. The original rotation was corn, wheat, clover and timothy, but this was changed in 1923 to corn, soybeans, wheat and clover, which is a more suitable rotation for this kind of land. All crops are removed except on plots 6, 7, 8, 10 and 11, where only the ear corn, wheat, grain, soybean grain, and clover hay are removed, leaving all the roughage except the clover hay on the land in lieu of manure.

The treatments shown in the second column of the table are as follows: L=ground limestone; P=phosphorus; K=potash; N=nitrogen; Res.=crop residue; O=no treatment; M=manure.

All limed plots received 3 tons of ground limestone per acre in the spring of 1917. The fertilizer applications consist of 72 pounds of phosphoric acid, 24 pounds of potash and 12 pounds of nitrogen per acre per rotation. To the end of 1928 the phosphorus and potash were equally divided between the corn and wheat, but the nitrogen is all applied for wheat, half in the fall and half in the spring. Beginning with 1929 the wheat receives two-thirds of the phosphorus and potash and nitrogen as formerly, while the corn receives one-third of the phosphorus and potash in the row and also 4 pounds of nitrogen per acre on the plots receiving complete fertilizer.

The manure applications consisted of 6 tons per acre plowed under for corn in the first round of the rotation. Since then the rate of manuring has been equal to the amount of produce removed during the previous round of the rotation, except the wheat grain.

The following table shows the results of different soil treatments begun in 1917:

PROGRESS REPORT—BEDFORD FERTILITY EXPERIMENT 1917-1929

AVERAGE YIELDS AND FINANCIAL STATEMENT PER ACRE PER ROTATION[1]

1. The crop rotation was changed in 1923 from corn, wheat, clover and timothy to corn, soybeans, wheat, clover.
2. Value of grain and hay increase due to residues alone.
3. Value of increase, cost and net for liming to date.
4. Value of increase due to manure used alone.
5. Value of increase per ton of manure.
6. Value of increase due to manure over lime.

NOTE.—In computing the financial results, corn has been valued at 60c, wheat at $1.25 and soybeans at $1.25 per bushel; stover and wheat straw at $2.50, soybean straw at $3.00 and hay at $10.00 per ton. Nitrogen has been charged at 20c, phosphoric acid at 7c and potash at 6c per pound. Ground limestone has been charged at $3.50 per ton.

Comparison of Different Phosphates

The object of this experiment is to determine the relative values of superphosphate, rock phosphate, bone meal, and basic slag as phosphatic fertilizers. Superphosphate and rock phosphate are also compared in several different proportions with and without lime, manure, nitrogen and potash fertilizers. The table following shows the results to date of treatments begun in 1916.

The largest returns have been secured from the combination of lime, manure, and heavy applications of superphosphate (plot

26). This treatment has produced average increases of 27.6 bushels of corn, 9.7 bushels of wheat, and 1,632 pounds of mixed hay per acre, valued at $39.74 per rotation or a total of about $185.46 per acre since 1916, when the treatments were begun, at a total cost of $37.52 for lime and phosphate. Fourteen dollars of this cost was for 4 tons of ground limestone, applied when the experiment was begun. (Compare plot 26 with 33.)

On limed and manured land superphosphate has been the most profitable source of phosphorus, the net returns per acre per rotation from the different phosphates averaging as follows: superphosphate, $13.53; basic slag, $13.13; steamed bone meal, $9.20; rock phosphate, $7.10. (Compare plots 2, 3, 5, and 6.) In this comparison superphosphate, basic slag, and steamed bone meal have been applied at the rate of 48 pounds of phosphoric acid per acre and rock phosphate at the rate of 192 pounds of phosphoric acid per acre with manure for each corn crop.

On limed land superphosphate has been more profitable than rock phosphate, whether used in large or small amounts and with or without manure. Without manure the superphosphate has averaged net returns of $9.97, and with manure $13.53, while rock phosphate has netted $3.40 without manure and $7.10 with manure per acre per rotation. (Compare plots 5 and 11 with 6 and 12.)

Without either lime or manure, rock phosphate has been more profitable than superphosphate, netting $17.35 against $12.09 for superphosphate (plots 14 and 15). On manured land without lime, rock phosphate is slightly ahead of the superphosphate, netting $18.49 against $18.45 for the superphosphate (plots 8 and 9).

On limed and manured land, rock phosphate applied at the rate of one ton per acre in 1916 and again in 1925, has produced crop increases to date valued at $56.60, while superphosphate applied at the rate of half a ton in 1916 and again in 1925 has produced increases valued at $79.66 up to the present time.

This field was laid out and tile drained in the summer of 1915. The crop rotation is corn, wheat, and clover with all produce removed except second growth clover.

The treatments shown in the second column of the table are as follows: L=ground limestone; M=manure; St. B.=steamed bone meal; BS=basic slag; AP=superphosphate; RP=rock phosphate; N=12 pounds nitrogen; K=50 pounds potash.

Ground limestone was applied at the rate of 4 tons per acre in 1915.

Manure was applied at the rate of 6 tons per acre for corn in the first round of the rotation and since then in amounts equal to the produce removed except wheat grain. The phosphates are applied at the rates shown in the third column in the accompanying table.

AVERAGE YIELDS AND FINANCIAL STATEMENT PER ACRE PER ROTATION

Plot No.	TREATMENT	Lbs. phos. acid per acre	AVERAGE YIELD PER ACRE			Total value of three crops in rotation	Value of increase due to fertilizer per rotation	Cost of fertilizer	Net gain due to fertilizer per rotation

(Plots 17, 18, 20 and 21 received 12 pounds of nitrogen and 50 pounds of potash per acre per rotation, all on the corn.)

1. Value of increase due to lime over manure.
2. Value of increase due to manure.
3. Value of increase per ton of manure.
4. Value of increase due to lime and manure.
5. Manured on Series B in 1916 and Series C in 1917.
6. Applied in 1916 and again in 1925.
7. Total value of increase, cost, and net returns to date at present prices.

NOTE.—In computing the financial results, corn has been valued at 60c and wheat at $1.25 per bushel; stover and wheat straw at $2.50, and hay at $10.00 per ton. Nitrogen has been charged at 20c, phosphoric acid at 7c and potash at 6c per pound. Rock phosphate (30%) has been charged at $15.00, and ground limestone at $3.50 per ton.

Variety Tests of Farm Crops

The selection of hardy, high-yielding varieties of the crops grown in any section is very important. To determine those best adapted for this part of the state, the most promising varieties of several crops have been compared each year for a number of years. Each variety has been harvested separately and the yields determined by weight. The land on which the variety tests are carried has been kept in a good state of fertility by uniform applications of fertilizer on wheat, and manure on each corn crop.

Pasture Experiments

The improvement of pasture land has a very definite place in the agricultural program for Southern Indiana. Large areas of this section are better adapted to pasture purposes than to its present use. There is a considerable area of pasture land that is not producing in a satisfactory way. The development of better pastures will make possible the expansion of the live stock industry from both the beef cattle and the dairy cattle point of view.

Several years ago a series of pasture experiments was laid out in one of the uniform spots of the old pasture, and the results given in the accompanying table indicate the value of this work. Further work will be conducted to study the most economical methods of pasture improvement.

Various grass mixtures were used in connection with the different fertilizer treatments, so some very definite information is available for those who are interested in this important work. In connection with this, lespedeza has been seeded on poor unproductive spots, and is gradually extending over the pasture land. Lespedeza seems well adapted to our poor lands, on which more expensive methods of improvement are not practiced.

RESULTS OF PASTURE EXPERIMENT, 1924-1929

Plot No.	TREATMENT PER ACRE*	Green forage pounds per acre 1924	Green forage increase over untreated	1925	Cured pounds per acre average 1926-29	Cured forage increase over untreated

* Treatments applied at seeding time in April, 1923, and fertilizer repeated in fall of 1929. Plots 2 and 9 receive top dressings of 100 pounds of nitrate of soda per acre each spring.

Farmers who visit the experimental field plots will see some new and interesting tests. Striking differences in the way different

A plot in the clover seed strain test which was practically killed out by the winter weather. Notice the excellent growth of surrounding clover. This emphasizes the importance of using hardy strains of red clover.

strains of red clover came through the winter show one reason for the increasing clover failures. The effect of broadcasting and row fertilization of corn and the effect of plowing under one year old sweet clover on the corn can also be seen.

These things together with the regular fertility results, variety tests of wheat, oats and soybeans, lespedeza and nitrogen top dressing of wheat will be seen on the field.

HORTICULTURAL EXPERIMENTS

The orchard is the largest single enterprise on the farm, consisting of 82 acres of apples, 1 acre of pears, 3 acres of plums and prunes and 4 acres of peaches. The original orchard was planted by Mr. Dunn and represents one of his major interests on the farm.

The Department of Horticulture under Professor Laurenz Greene, chief, cooperates in the management of the horticultural work and supervises their experimental projects on the farm, Professor C. L. Burkholder giving this part of the work his personal attention. He reports their work as follows:

Stationary vs. Portable Spraying

In the spring of 1930 an up to date stationary spray plant was installed on 50 acres of the north section of the apple orchard. This area is very rough, cannot be cultivated and has always been very difficult to spray with portable rigs. In addition to this farm problem, many fruit growers in the vicinity of Bedford, as well as in all sections of Indiana, are very much interested in the merits of stationary spraying in comparison to the use of portable rigs. With this question in mind the 30 acres of apple orchard on the south section of the orchard are being handled by a new large capacity portable sprayer. Careful records have been kept for three years on the cost and amount of material applied to these blocks with portable rigs. It is too early to draw any conclusions as to the merits of the two widely different systems of spraying, but a few statements from 1930 figures are interesting:

1. It cost $1,617.52 to buy and install the stationary plant complete except motor.

2. All labor, except electrical work, was done by regular farm force. It took 423 hours of man labor, 66 hours of horse labor and 6 hours of truck labor. Wiring plant cost was $33.40. Total labor and wiring bill was $174.70.

The new stationary outfit was installed this spring to spray 50 acres of the orchard.

3. Total cost on acre basis was $32.35 without motor. Acre cost could be reduced by piping entire apple orchard to present plant.

4. With old model portable rigs the application of from 1,200 to 1,400 gallons of material was an average day's work. In the case of the new high powered portable rig now being used, from 2,000 to 2,400 gallons is the average day's application. This is a gain of from 1,000 to 1,200 gallons per day with no added cost for man or tractor labor.

5. With the stationary plant the entire fifty acres is covered from one side in 6 to 7 hours using from 3,300 to 4,000 gallons of material. It requires one man at the tank, two men with guns without hose carriers and one man with gun and an extra man to carry his hose in the roughest section of the orchard. This makes a total of five men.

6. In 1929 on the petal fall application it took 102 man hours, 29 horse hours and 19½ tractor hours to apply 4,900 gallons of material to the area now covered by the stationary plant. In 1930 it took 50½ man hours to apply 7,800 gallons to the same block. It would seem that more material is being used under the stationary system than was formerly used with the portable rigs.

Plum and Pear Orchard

This will be the third growing season for the plum and prune orchard composed of about twenty promising varieties. Not a tree has died in the block. Some interesting facts regarding varieties suited to the Bedford area are sure to come from this test.

Blight has practically destroyed all commercial pear plantings in Indiana. In recent years new methods of handling pear trees have been found to be at least partially successful in controlling blight. It seemed that there might be a good chance of these methods working under Indiana conditions and a test planting was made in 1930. This test is under the management of Mr. McCown of the Purdue Horticultural Department. Resistant root stocks were used and on these the Old Home variety was grafted. This will give a root system, body and scaffold limbs which in other sections have shown resistance to blight. Several of the best commercial varieties of pears will be grafted 18 inches or two feet out on the scaffold branches of these trees in 1932.

Peach Orchard

Peach fruit buds were killed on all varieties everywhere in Indiana this year. This condition offered an opportunity to cut back all peach trees very severely and renew the fruiting area of the tops. A nice growth of new wood is putting out on these trees and they are worth seeing. Winter injury to the bodies of these trees was severe and a few trees are badly cracked up and down the body. On the whole, the orchard is recovering nicely considering the fact that none of the land on this farm is ideal for peach growing.

Soil Management in Apple Orchard

For a long period of years the north half of the apple orchard has been in sod while the south half has been cultivated and cover cropped. On account of severe washing and failure of cover crops

The Elberta peach orchard after pruning. The severe winter killed the fruit buds and the orchard was given a severe pruning to prepare it for next year.

Heavy applications of mulch were placed under many of the trees last summer when part of the orchard was sown to grass.

in recent years the south area was seeded in the spring of 1929, using a combination of Japanese Clover, Alsike, timothy, red top and blue grass. In the spring of 1930 sulphate of ammonia at the rate of 150 pounds to the acre was broadcast between the rows instead of scattered under the outer branches of the trees. A very fine growth of grass and clover has resulted and this will be cut and allowed to lay where it falls as a mulch.

Apple Storage

Apple storage studies were continued by C. E. Baker of the Department of Horticulture and I. D. Mayer of the Department of Agricultural Engineering. The results of this work from 1926 to 1929 are given in detail in the Report of the Moses Fell Annex Farm of 1929.

This work was continued during 1929-1930 and is mainly a test of the keeping quality of apples in an uninsulated room cooled by ventilation compared with the same number of crates and varieties held in an insulated room cooled with a bunker of ice similar to that used in a railroad refrigerator car. Grimes and Jonathan are the varieties used in this test. The following temperature relations prevailed during the past season.

	Weekly Average of Daily Mean Temperature During Period Ice was used		
1929	Iced Room	Vent. Room	Diff. in favor of Ice
Sept. 14-16	49.5°	63.7°	14.2°
Sept. 16-23	43.8°	55.0°	11.2°
Sept. 23-30	44.7°	61.3°	16.6°
Sept. 30 to Oct. 7	45.4°	52.4°	7.0°
Oct. 7-14	46.1°	54.4°	8.3°
Oct. 14-21	45.5°	50.9°	5.4°

Cost of ice on bushel basis for September was .095 cents; and for October the cost was .045 cents.

Early in the season the apples in the iced room have a distinct advantage and ripen much more slowly than in the ventilated room. Both varieties shrivel more rapidly in the ventilated room in spite of keeping the soil under the floor in the ventilated room thoroughly wet down at frequent intervals.

However, under the market conditions prevailing in most sections of Indiana in October and November of 1929, all the Grimes and Jonathan could have been sold early and there would have been very little difference in the actual value of the fruit from the two rooms based on early sales. On December 16, 1929, 35 crates of each variety from both rooms were graded out and sold. Mr. Baker reports, "There was 4 per cent more sound fruit in the iced room and the difference in quality and appearance in favor of the fruit from the iced room was still very evident."

A large commercial grower at Mitchell is using the same methods on an uninsulated storage. He feels that it pays good returns especially in heavy crop years when No. 2 grades move slowly in the early part of the selling season.

Ice Cold Cider

In 1929 Mr. Hienton of the Department of Agricultural Engineering installed an electric refrigerator plant on the sales floor of the packing house. This was used to store gallon bottles of cider. This ice cold cider proved to be very popular with the local buyers. It was possible to hold cider two weeks very nicely and it probably could have been held even longer. All of the "cider" grade of fruit from a 5,000 bushel crop was profitably made up into cider. Still the demand was not entirely met.

Spray Schedule

Each year a variation from the standard spray schedule is used on large areas of the apple orchard. Valuable experimental findings in the control of insects and diseases are continually being made by the Entomology Department at Purdue and in other states. Often these tests are on very small plots of one or two varieties. By trying these new sprays out in a large way their practical use in commercial orchards is further tested. The new oil-nicotine spray for second brood codling moths will be used on the entire orchard this year and chemical analyses will be made to determine the amount of arsenic on the fruit at picking time.

POULTRY EXPERIMENTS

The development of the Barred Plymouth Rock flock has been satisfactory. Accurate records are kept on all birds in the large house as a part of the Record of Performance work. One of the pullets laid 281 eggs during the year and a number of others have a record of more than two hundred eggs.

Mr. Hughes showing "Lady Antoinette" who made a record of 281 eggs last year.

The young chicks for this year have been produced from special breeding pen headed by males from high producing hens Regular blood tests have been made on the breeding flock to kee it as free as possible from disease.

All of our chicks have been hatched on the farm in the electri incubator. The trays, etc., are all washed and disinfected betwee hatches to insure healthy stock. The brooder houses are move each year to clean soil and are located this year in the orchard jus west of the large poultry house.

The equipment in the house represents in a fair way the idea of the Poultry Department under the direction of Professor C. W Carrick, chief. Mr. S. A. Walford of that department visits th farm as often as circumstances permit and advises regarding th management of the flock.

Brooder houses on clean ground in the orchard. Sanitation is an important item in producing healthy young stock.

LIVE STOCK EXPERIMENTS

It has been the policy on this farm to develop the crop producing power of the land by using methods recommended by the Department of Agronomy and to utilize these crops to feed good live stock. In our live stock work we have had the advice and cooperation of Professor F. G. King, chief, and Claude Harper, assistant chief, of the Department of Animal Husbandry.

A herd of Shorthorn cattle has been produced from a very modest beginning several years ago. Southern Indiana has large areas of hill and pasture land which could be available for cattle production. The effort here has been to produce a herd of good beef cows that swing good udders and produce well at the pail. Progress is always slow in such work and with the view of proceeding on a larger, more valuable program as rapidly as possible, the Agricultural Experiment Station has approved and established a cooperative project with the Bureau of Animal Industry of the United States Department of Agriculture, which, if successful, will ultimately develop one of the finest herds in America from the standpoint of dual purpose cattle.

Sheep

The following report of the flock of sheep by Professor Claude Harper gives some interesting facts about the sheep on the Moses Fell Annex Farm.

Early in 1922 a small flock of sheep was placed on the Moses Fell Annex Farm. They were placed there primarily to help rid the pastures of weeds, briers and sprouts. This flock of grade Shropshires was purchased from the Pinney-Purdue Farm near Wanatah. At the end of a year it was observed that many of the ewes were losing wool which caught in the brush, briers and thickets where the sheep were grazing. Furthermore, these ewes were not eager grazers of briers and shrubs.

Shearing Merinos on the Moses Fell Annex Farm. The use of a 1/4 h. p. electric motor on the shearing machine provided a steady, uniform power for operating the clippers.

In 1923 it was decided to select a type of sheep carrying some fine wool blood so the wool would not pull on the brush and briers, and at the same time attempt to obtain a type of sheep that would better graze the weeds, briers and shrubs in the pastures.

This situation resolved itself into the selection of either Ohio Delaines or ewes of a western type. Each contained fine wool blood. The Delaines were Merino and the western ewes contained a predominance of Rambouillet breeding.

During the World War there had been much talk about increased wool production in America. Between 1915 and 1921 wool growers had received good prices for their product. Fine wools had commanded a premium. Ohio Delaine sheep were sold extensively in Indiana by speculative dealers. Many claims were being made by dealers relative to the merits of Delaine Merino sheep as producers of market lambs and wool.

Purdue University had had no experience with Merino sheep, and the questions being asked at that time could not be discussed with a definite knowledge. When the question of the type of fine wool sheep to be selected was discussed it was urged that a study of the adaptability of Delaine Merinos be made at the Moses Fell Annex Farm for areas of Indiana similar to the type of land found in Lawrence County. Hence, a car load of something over one hundred Delaine Merino ewes was purchased in the winter of 1923 at a cost of $8.00 per head.

Previous experiences with losses of sheep and lambs by white snake root poisoning, stealing and predatory animals made it advisable to buy sheep as cheaply as possible. For the most part, the ewes purchased were of good quality with some rather old ewes in the group. There were a few two and three year olds, but the majority were full mouthed. A few of these original ewes are still on the Moses Fell Annex Farm.

The first year these ewes dropped lambs sired by both fine wool and mutton type rams. The following year they were bred to both Shropshire and Delaine rams. During the past six years only Delaine rams have been used as breeding sires. Within a year after the ewes came to the farm, the flock was reduced to 65 to 75 high grade Delaine Merino ewes, their lambs and a few purebred ewes.

Within a short time after these Merino sheep came to the farm a severe outbreak of foot-rot was discovered. Nearly all the ewes had one or more hoofs infected, and three-fourths of the lambs had foot-rot infection. It was quite evident that this disease came with the sheep. A half dozen or more ewes were lame when unloaded from the car, and the outbreak came on so rapidly, it will long be remembered that with this original group of Merino ewes came foot-rot. It took a year and a half to completely rid the flock of this disease. By trimming the feet regularly every three months, the opportunity for foot-rot to develop is greatly reduced.

In 1926 a half-dozen purebred ewes were added to the flock. Several of these ewes and their offspring have been killed by dogs. Some of these ewes have always produced weak lambs at birth, most of which died. Others have been poor sucklers. Hence, the purebreds have not multiplied at any great extent.

During the time the Delaine Merinos have been on the Moses Fell Annex Farm the lamb crop raised to a market weight has varied from 40 to 65 per cent. There has never been a 100 per cent lamb crop born. Many lambs have been lost at lambing time. Even though the flock was well fed and managed during the gestation period some lambs were born weak. Seldom have twins been raised, and a large percentage of the ewes have been rather poor milkers. Great difficulty has been experienced with new born lambs to get them to suckle their mothers. It has been necessary to keep these high grade Merino lambs until they are ten to fourteen months of age to get them to an average weight of 75 pounds per head. All these conditions concerning lambs apply to the high grade and purebred Delaine Merinos.

Where cross-breds have been produced, the story has been somewhat different. Shropshire-Merino cross-bred lambs have been stronger at birth, more anxious to suckle their mothers when only a few hours old, and reach a 75 pound weight in six to eight months after birth while grazing on fair pasture.

During the past five years this flock has produced $2,887.00 in cash sales of wool, lambs and sheep. This is an average of $577.40 per year. The gross sales of wool during that time have totaled $1,970.24 or 68 per cent of the total gross returns during the past five years. The sales of sheep and lambs have totaled $916.76 during the past five years, or 32 per cent of the total gross returns from the flock.

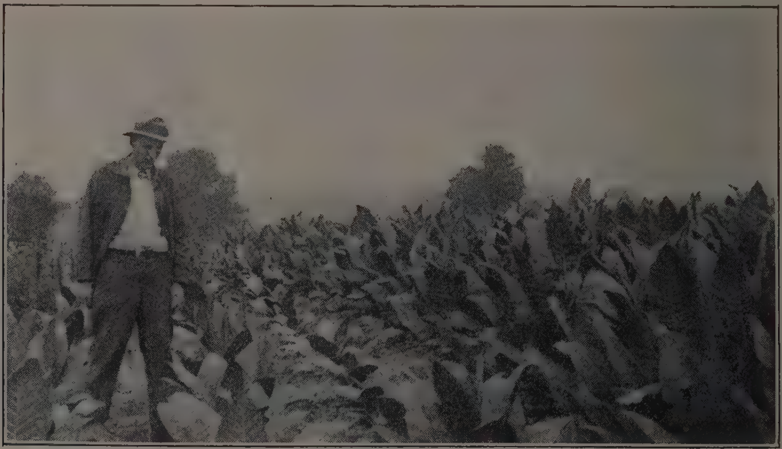
These ewes have produced a good clip of wool every year. The ewes have averaged approximately ten pounds of grease wool per head per year. During the past five years the wool from the ewe flock has graded 70 to 80 per cent Delaine, which is the finest grade of market wool produced in the world.

TOBACCO EXPERIMENTS

The preliminary experiments to study the response of tobacco to fertilizers have been continued. Two acres of old sod were turned under for this work. Young plants, variety Kelly, were produced in the usual way and transplanted to the plot.

The weather conditions were not ideal to give maximum results from the fertilizer, but the differences in yield are sufficient to emphasize the value of fertilizer.

The tobacco was dusted to protect it from insect damage.

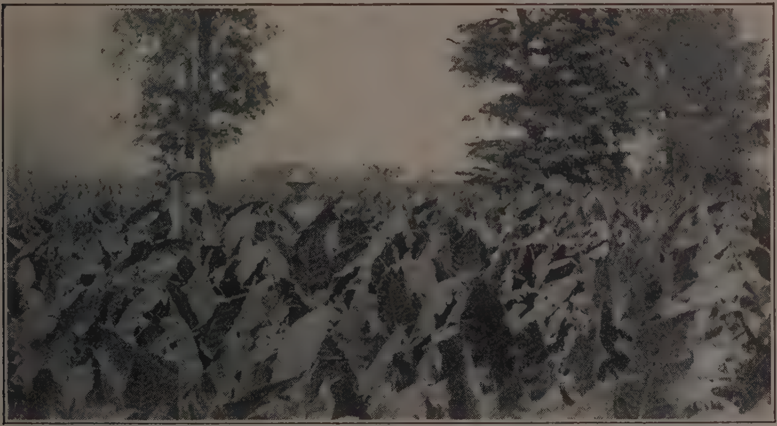


Comparison of plot having no fertilizer (left) with plot receiving 500 pounds per acre (right). Picture was taken August 7, 1929.

It was topped a little higher this year than last in an effort to improve the quality.

Plot No.	Fertilizer Per Acre	Yield per acre	Graded as Follows:					
			Leaf	Trash	Lugs	Red	Tips	Flyings
1	1,000 lbs.	1,578	358	378	320	152	316	54
2	500 lbs.	1,143	178	363	188	124	275	15
3	250 lbs.	1,012	86	198	154	172	292	110
4	500 lbs.	1,112	240	212	228	180	252	......
5	none	920	100	80	120	160	260	200

The fertilizer used was a 6-15-9. It is interesting to note that the fertilized plots had a much lower percentage of tips and flyings than the untreated plot. Lack of moisture during the summer no doubt reduced the yields of all plots. The results of two years' work would suggest that an application of 500 pounds per acre of high grade fertilizer gives profitable returns. The work is being continued this year.



A view of the plot receiving 1,000 pounds per acre. This tobacco graded out well with only 23.4 per cent as tips and flyings.

RELATION OF ELECTRICITY TO AGRICULTURE

The study of the use of electricity as a source of power has been conducted on the farm. The cost of grinding feed, pumping water for spraying and for live stock, operation of stationary spray outfit, shearing sheep, hatching chicks, operating fruit grader, washing machine and iron, cooking, refrigeration and lighting is determined through the use of special meters. Electric lights in the poultry house have increased the egg production during the winter months. Excellent hatches have been obtained from the electric incubator.

ACKNOWLEDGMENT

The farm is being operated for the benefit of the farmers of this section. The soil type represents a very large section of the southern part of the state and the results of the experimental work may be applied throughout that section.

Purdue University wishes to acknowledge the helpful cooperation of the various farm bureaus, the County Agricultural Agent, the banks, the Home Economics Clubs, Kiwanis Clubs, Rotary Clubs and other organizations and individuals of Lawrence and neighboring counties. This cooperation extends the value and usefulness of the farm.

The insectary which was constructed in 1927 as a laboratory for the codling moth studies. This work is essential to the development of efficient methods for the control of the codling moth which is a serious menace to the fruit growers of southern Indiana. The Department of Entomology has a number of other plots near Mitchell.

Showing condition of the orchard before the reclamation work was commenced. Many parts of the orchard were much worse than this. The trees were crowded and starved and more than half of the apple trees were dead.

A view of the orchard after it had been pruned, sprayed and cultivated. Much of the orchard is now down in grass and the trees are fertilized each year.

The packing and storage shed make it possible to handle, grade and store the fruit produced on the farm. The crop can be disposed of as the community needs it. This permits a more economical method of handling the crop and renders the community a service.

A field of alfalfa as it appeared about time for the last cutting. Alfalfa has proved to be a very satisfactory crop on the farm.

INSTALLATION OF MOTOR-DRIVEN FEED GRINDERS

TRUMAN E. HIENTON

The increase in the number of Indiana farms which are being served from farm electric lines has resulted in a corresponding increase in the number of motor-driven feed grinders on them. This increase in use of electric power for operating feed grinders may be partially attributed to the ease and readiness of starting electric motors, economy of operation, and high speed necessary for satisfactory operation of hammer-type grinders.

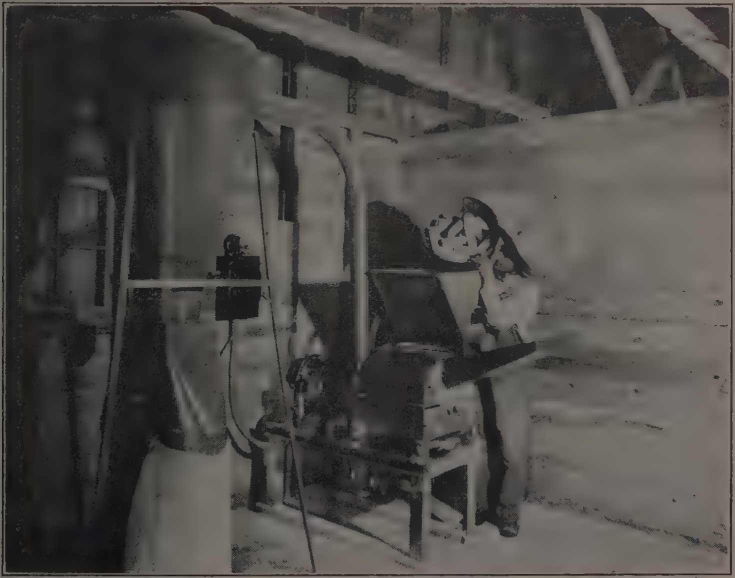

Figure 1. A direct-connected motor drives the feed grinder and the attached blower on the farm of Shelbert Wright, Clinton, Indiana.

The location of a motor-driven feed grinder on the farm is affected by several factors. The construction and location of grain bins and corncribs, location of bins for ground grain, and construction and equipment of the building in which the grinder is to be used, all affect its location.

A considerable amount of labor is saved in the type of installation shown in Figure 3, where the grinder is located under the grain bins and corn or other grain is fed into the mill by gravity. This installation is probably the most efficient from the standpoint of saving labor. It does necessitate the use of an elevator to raise the grain into the overhead bin.

Other labor-saving methods of installation are shown in Figures 2 and 4. An inexpensive box shown in Figure 2 increases the capacity of the hopper on the grinder and eliminates the necessity for constant attention to filling it. In Figure 4 a large box has been located just above the hopper of the grinder and is so arranged that a constant supply of grain passes from it into the hopper.

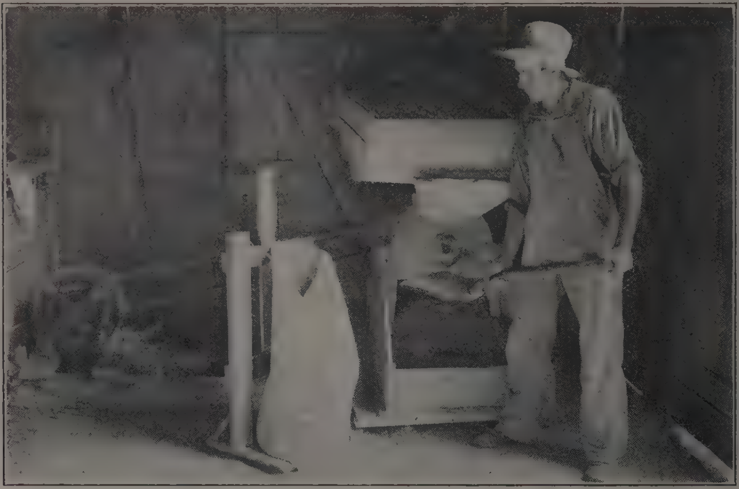

Figure 2. A small storage bin built under the grinder allows ground grain to collect between sackings on the farm of Maurice Beisel, Cambria, Indiana.

Where it is not possible to locate the grinder under or adjacent to grain bins or corncribs, its location will undoubtedly be determined by the location of the ground feed bins. Locating the grinder directly above the feed bin or beside it may eliminate one-half of the labor required in grinding which is spent in handling the ground feed.

One very practical method of eliminating labor of handling ground grain, although limited in application, is that shown in Figure 4, where the ground grain drops from the mill, mounted on the mow floor, directly into the feed box on the floor below. This type of installation, however, is usually confined to bank barns.

Where building construction does not permit of the gravity method of disposing of ground grain, a blower or elevator may be used to move the grain away from the grinder. The blower shown in Figure 1 elevates the grain from the grinder into the dust collector and bagger. Overhead feed bins are often used for storage of grain where a blower is available.

The elevator visible in the right foreground of Figure 3 lifts the grain from the grinder to a height sufficient to drop it into a wagon box or into the top of a feed storage bin. Where none of this equipment is available and type of barn construction does not permit, the grain is scooped away from the grinder as shown in Figure 2. The construction of a small storage bin around the grinder permits the ground grain to accumulate for some time and eliminates the necessity for constant scooping. It is entirely possible and practical by raising the grinder higher off the floor to put casters on this bin and use it as a portable feed box.

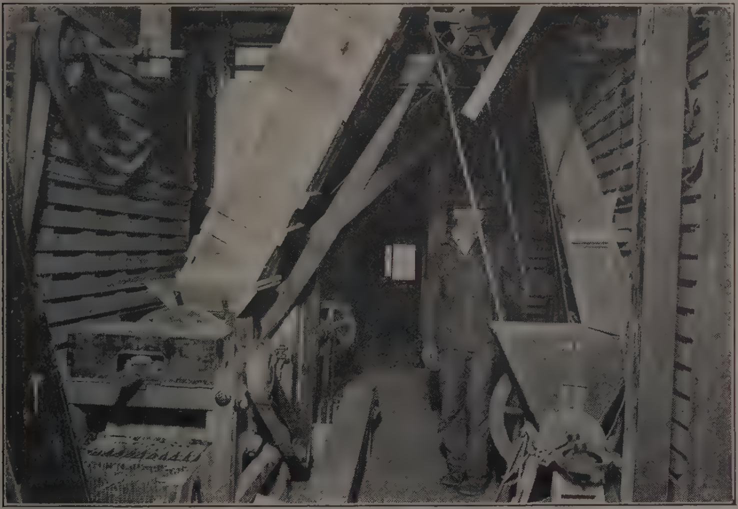

Figure 3. All grain ground on the farm of Ed. Layden, West Point, Indiana, passes from overhead bins directly to the grinder, then to the feed bin without necessity of handling.

Location and selection of motor.

No type of power permits of the flexibility possible in location of the power unit as does that derived from electric current. A motor may be installed on the floor, wall, or ceiling and be expected to operate satisfactorily if properly installed and of the proper type.

Where a motor is to be used for driving the grinder alone, it may be directly connected as shown in Figure 1. In such cases the use of the motor is limited entirely to that of operating the grinder. This prevents its use for other occasional farm power operations for which it might be suited.

Belt drive is used for the majority of motor-driven feed grinders on the farm. By the use of pulleys of proper size, direct drive is satisfactory for the high-speed hammer mills, as well as slower speed burr grinders. A convenient method of mounting motor and grinder is shown in Figure 2 where both are fastened to two 4" x 4" timbers with lag screws. The tension of the belt is changed by sliding the motor on the base or rails upon which it is mounted. An outfit of this type may be moved about the farmstead rather easily by sliding it on these skids.

UNIVERSITY

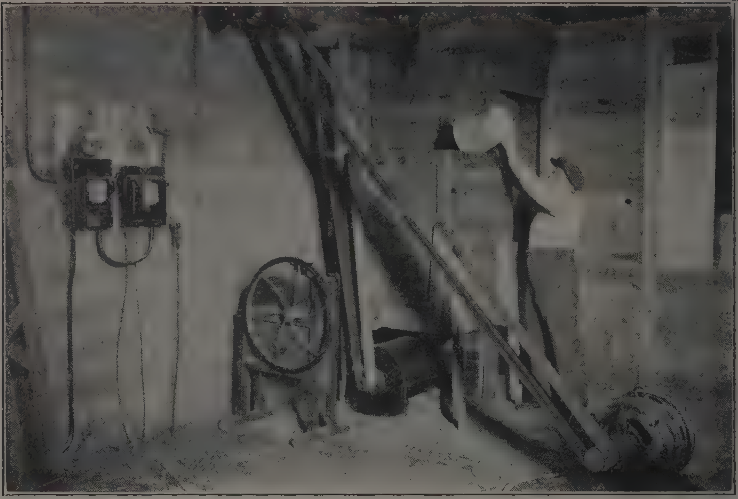

Figure 4. Ground grain drops directly from the grinder into the feed bin on the ground floor of the bank barn located on the farm of O. C. Hendrix, Burlington, Indiana.

On many farms where the installation is to be made in a permanent building, the motor may be located so as to drive other machinery besides the grinder. In some cases the drive to the grinder is direct from the motor and in others through a system of shafts and pulleys. In Figure 4, the motor is installed to drive a shaft which in turn drives the grinder or corn sheller. A motor not visible in Figure 3 may drive a cup elevator, floor drag, grinder, sheller, or ground grain elevator through one or more countershafts.

The size of motor necessary for operating feed grinders on the farm varies from 2 to 10 horsepower. The common sizes are 2, 3, 5, and 7.5 with an occasional 10-horsepower motor. The 5- and 7.5-horsepower sizes appear to be best suited for farms where large amounts of grinding are done. Those shown in Figures 1, 2, and 4 are of 5-horsepower and the one used in the installation shown in Figure 3 is of 7.5-horsepower capacity. Motors of this size are almost invariably operated at 220 volts and are usually for single phase, 60 cycle current. The speed of the motor should be 1,800 R. P. M. except in certain cases where direct connected, and in some of these a 3,600 R. P. M. motor may be used.

OPERATING ENSILAGE CUTTERS AND HUSKER-SHREDDERS WITH ELECTRIC MOTORS

TRUMAN E. HIENTON

Many new farm electric lines are furnishing electric power to Indiana farms, making possible the operation of ensilage cutters and husker-shredders with electric motors. Experiments which have been conducted by the Agricultural Experiment Station on Indiana farms show the practicability of operating either of these machines successfully with an electric motor.

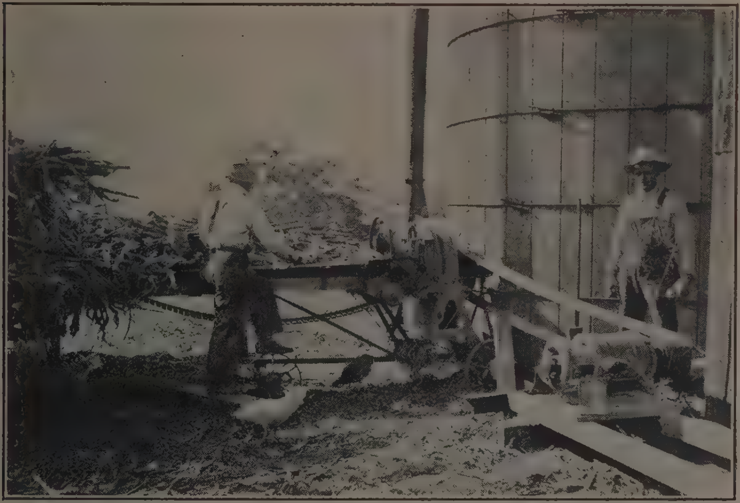

Figure 1. Filling the silo with a 5-horsepower electric motor operating the cutter on a farm in Fountain County, Indiana.

In September 1927, 13-inch ensilage cutters of three different makes were used to determine the practicability of driving them with a 5-horsepower electric motor on a farm in Clinton County. The results of these tests are listed in Table I. In all of the tests the cutter was fed so as to use as nearly as possible the rated horsepower of the motor. In several of them, as will be noted, the average horsepower was somewhat less than the rated horsepower and in two cases slightly above.

During 1928 and 1929, seven Indiana farmers filled their silos using 5-horsepower electric motors to operate their 13-inch ensilage cutters. Records secured on these farms indicate that 0.8 to 1.25 kilowatt-hour is required per ton of silage cut and elevated.

TABLE I—TESTS OF 13-INCH ENSILAGE CUTTERS DRIVEN BY A 5-HORSEPOWER ELECTRIC MOTOR

Cutter	Speed R. P. M.	Length Cut in.	Tons Cut	Capacity Tons per hr.	Ave. Hp. output motor	Kw.-Hr. per ton	Comments
No. 1	470	½	5.46	4.85	5.19	1.01	3 sharp knives
No. 1	430	½	12.83	5.83	5.09	.826	3 sharp knives
No. 2	430	½	12.97	5.46	4.81	.833	3 sharp knives
No. 3	470	⅜	11.57	5.14	4.94	.908	3 sharp knives
No. 3	470	½ to ⅝	3.85	4.15	4.11	.935	2 sharp knives
No. 3	470	½ to ⅝	6.81	3.53	4.49	1.20	3 dull knives
No. 3	470	½ to ⅝	5.18	4.4	4.85	1.04	3 sharp knives

Observations made during the tests in 1927 and on some of these farms in 1928 and 1929, indicate certain important factors to be observed when a 5-horsepower electric motor is used to drive the ensilage cutter.

1. Sharp knives should be used, changing them twice daily, that is at the start of the day's work and at noon. The knives should be kept properly adjusted with regard to the shear plate, the stationary plate against which they cut. They should be set so as to run as closely as possible to the shear plate without striking it.

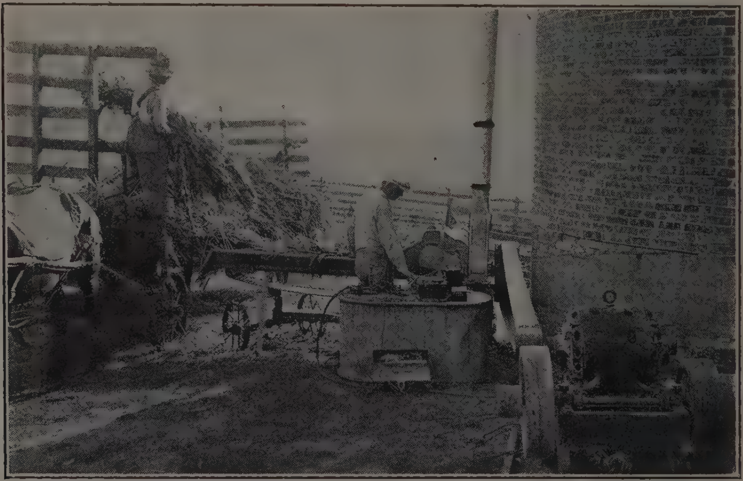

Figure 2. Determining the capacity of a 13-inch ensilage cutter when driven by a 5-horsepower motor in Clinton County.

2. The shear plate should be replaced when the edge becomes worn or rounded off. These are usually reversible, that is, they may be turned over and continued in use.

3. The motor should be of 5-horsepower capacity, 1800 R. P. M., 220 volts, single phase (unless three-phase service is available) and 60 cycle (unless other must be used). A 7.5-horsepower motor may be advisable where 16-inch or larger cutters are used, but should be avoided because of usual additional capacity charge. It should be equipped with a magnetic switch provided with a thermal overload relay. Wires carrying service to the motor should be at least No. 6 or larger if necessary because of excessive voltage drop and should be installed by a competent electrician or power company representative. Drive will ordinarily be by belt, which should be from 4 to 6 inches wide of 4-ply stitched canvas or rubber or single-ply leather. Motor pulley should be of fibre or paper, usually 4½ inches in diameter with face for 6-inch belt. Motors mounted on a truck are frequently easier to get into proper position but not entirely necessary.

The above have been supplemented by recommendations of Professor F. W. Duffee, University of Wisconsin, and are presented here.

4. The speed of the cutter should be as slow as will elevate the corn into the silo at full load. Many cutters of older design will not elevate at speeds as slow as the newer cutters, and must be operated at speeds considerably above those given in Table II.

TABLE II—Ensilage Cutter Speeds for 5 H. P. Electric Motors

Table of cutter speeds for most efficient operation for different sized elevating fans and for silos of different heights

Diameter of Cutter Fan	Height of Silo								
	25′	30′	35′	40′	45′	50′	55′	60′	75′
	Revolutions per minute of cutter fan								
36″	415	440	480	510	540	575	600	625	695
38″	390	415	450	480	510	545	570	595	660
40″	370	395	430	460	485	515	540	565	625
42″	355	380	410	435	465	490	515	535	595
44″	340	360	390	415	440	470	490	510	570
46″	325	345	375	400	425	450	470	490	545
48″	310	330	360	380	405	430	450	470	520

Note: These speeds are based upon carefully conducted tests with a reasonable allowance to insure uninterrupted elevation. Good cutters will positively operate at these speeds.

5. Size of Cutter.

The 12- or 13-inch cutter is best suited for use with the 5-horsepower motor. Larger cutters may be used where height of elevation is not great but only with very careful feeding. The clearance at the tip of the fan wings should not exceed ⅛ inch and at the sides not over ½ inch.

Husker-Shredder

The annual flight of the corn borer with the resultant increase in area which it infests may result in a similar spread in the practice of shredding corn stover in Indiana. It has been found that the husker-shredder is very effective in destroying borers in corn stover where such machines are properly adjusted.

Lack of information concerning the use of electric power to operate husker-shredders was responsible for the initiation of tests by the Agricultural Experiment Station in November, 1928. The first tests conducted on a Huntington County farm were made to determine what size

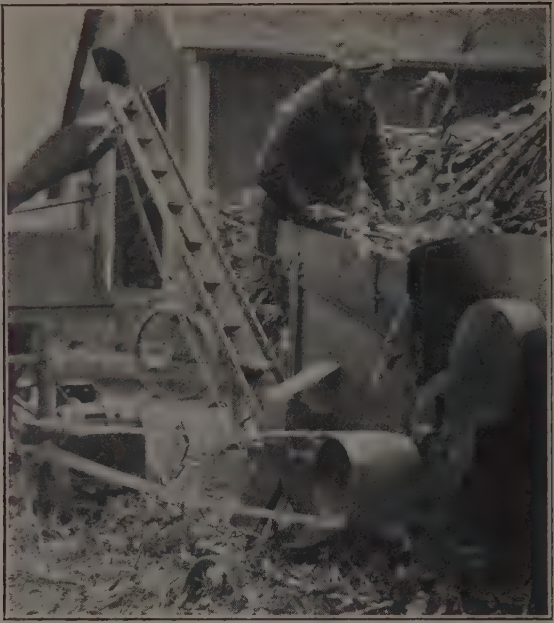

Figure 3. Husking and shredding with a 2-roll machine operated by a 5-horsepower motor in Huntington County.

of husker-shredder could be operated by a 5-horsepower electric motor. The results indicated that a two-roll machine was the largest size which could be operated by a motor of that capacity.

During February 1929, the tests were continued using a 5-horsepower as well as a 7.5-horsepower motor to operate the two-roll husker-shredder. The results listed in Table III indicate that very little additional capacity could be secured by using the 7.5-horsepower than the 5-horsepower motor with this particular machine.

TABLE III

Motor H. P.	Stover Shredded T.	Corn Husked Bu.	Capacity per Hr.		Kw.-Hr. Per Ton Stover	Ave. Power output motor.
			Bushels Husked	Stover Shredded T.		
5	3.77	51.1	13.2	.972	5.13	5.34
7.5	7.78	102.9	14.5	1.096	4.97	5.70

The results of these tests indicate:

1. The practicability of operating a two-roll husker-shredder with a 5-horsepower motor.

2. The possibility of operating a four-roll husker-shredder to a limited capacity with a 7.5-horsepower motor.

ARIZ.UNIV.LIB. APR 17 1931

Circular No. 175 July, 1930

INDIANA PLANTS INJURIOUS TO LIVESTOCK

THE SUCCULENT 2-LEAF COCKLEBUR SPROUTS ARE FATALLY POISONOUS TO HOGS, SHEEP AND YOUNG CATTLE PARTICULARLY ON MOIST LAND DURING SPRING
DESTROYED

Fig. 1—A Purdue exhibit featuring cocklebur sprout poisoning.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

Illness and death of livestock due to poisonous plants are factors that cannot be ignored in Indiana. Field investigations on 420 farms in the state have established that white snakeroot, cocklebur sprouts, water hemlock and wild cherry are the most important toxic species in Indiana, although the aggregate loss caused by sweet clover hay, black locust bark, the staggerweeds and buckeye sprouts and nuts is heavy. In addition a number of miscellaneous plants such as Jimson weed, nightshade, scouring rush, and peach foliage occasionally cause trouble.

Where circumstances indicate forage poisoning on the farm a competent veterinarian should be consulted immediately. The Purdue University Agricultural Experiment Station is always glad to co-operate in locating the cause of the trouble by identifying specimens of plants under suspicion and by giving other assistance that may be necessary. Practical suggestions on methods of locating poisonous plants on the farm are given.

A brief description of the plant and the symptoms it produces is given for the following species of poisonous plants, arranged in the order of their importance in the state: white snakeroot, water hemlock, wild cherry, cocklebur, black locust, staggerweeds (Dutchman's breeches and dwarf larkspur), buckeye, Jimson weed, deadly nightshade and pokeroot.

The less important poisonous plants discussed are scouring rush, mandrake, ergotized rye and grasses, rhubarb (leaves), castor bean, water lily, Kentucky coffee tree, sneezeweed, black-eyed Susan, wild indigo, cockle, buttercup, prickly ash, cat-tail, whorled milkweed, water parsnip, winter cress, groundsel, button bush, star of Bethlehem, red sorrel, bull nettle, bittersweet, matrimony vine, oak, and peach (leaves).

Cultivated plants that are dangerous under certain conditions are sweet clover, alsike clover, sorghum, Sudan grass, Johnson grass, and potato.

Mechanical injuries are caused by balls or solid masses of plant hairs, awns or stalk fragments, and by barbed beards or hairs and burs or spines.

INDIANA PLANTS INJURIOUS TO LIVESTOCK

By Albert A. Hansen[1]

Botany Department, Purdue University
Agricultural Experiment Station

Mysterious loss of livestock on pasture has been so common an experience in Indiana that farmers have learned to accept these losses philosophically. During the past few years, however, investigation has revealed that a number of plants common in Indiana woods and pastures are dangerously poisonous to farm animals and suspicion is directed to forage poisoning as the probable cause of many of these hitherto unexplainable losses.

With this theory in mind a unique project was started by Purdue University Agricultural Experiment Station in which the botanist with his knowledge of plants joined forces with the veterinarian with his knowledge of animals. This project involved the inspection of farms in all parts of the state on which local veterinarians reported livestock losses under circumstances indicating plant poisoning. During the past seven years 420 such farms have been inspected by the writer, usually in company with the attending veterinarian, and on 242 of these farms on which a total of 614 sheep, 381 cattle, 191 hogs, 69 horses and mules and 81 goats died from what was diagnosed as plant poisoning, the toxic species believed to have been responsible for the trouble were located, the symptoms displayed before death, evidence of grazing on the poisonous plants and the general circumstances under which poisoning occurred being the basis of these conclusions.

The field work, combined with experimental evidence, is the principal guide used in selecting the data upon which this circular is based. Only poisonous plants that have been found to be causing trouble on Indiana farms are included and they are arranged in the order of their importance as indicated by the work in the field.

---

[1] Valuable cooperation during the course of this work was given by the Veterinary Department of the Purdue University Agricultural Experiment Station and by the Indiana Veterinary Medical Association. Mr. O. C. Lee assisted in the preparation of this circular.

The majority of the species herein considered have been demonstrated to be poisonous by experiments but considerable variation in poisonous properties and effects exists. This variation may be due to the soil. In the case of white snakeroot, a test has been developed that indicates the amount of poison contained in the individual plant. The application of this test shows marked variation in the amount of the poisonous principle contained in plants growing in different localities. Two extremes are shown by specimens from the vicinity of Lafayette, Indiana, which were found to be highly toxic, while plants near Washington, D. C., are practically harmless. The factor can hardly be climatic since farther south in North Carolina and Florida white snakeroot is fatally toxic.

Seasonal variation in the drug content of plants also exists as commercial growers of drug plants have learned. Then, there is individual immunity or resistance among animals, a factor frequently noted, which may be inherited or may be acquired in the same manner that a human morphine addict may take sufficient of the drug to kill an ordinary person with little apparent harm. The appetites of different animals also vary, some members of a herd seeming to ignore poisonous species that are eagerly devoured by others. Furthermore, a species dangerous to one kind of farm animal may be harmless to others as in the case of dwarf larkspur, which does not affect sheep but is fatal to cattle. For these various reasons the presence of poisonous species on a farm is not always followed by livestock losses but plants of this character should always be looked upon as potentially dangerous and treated accordingly. There are literally hundreds of farms in Indiana with woodlots badly infested with white snakeroot upon which no losses have been experienced for a generation, but a sudden drought or some other factor may become responsible for considerable trouble.

PREVENTION OF POISONING

1. Eradicate the poisonous plants where practicable or else do not allow the animals to graze on infested areas.
2. Practise good feeding methods. It has repeatedly been noted that animals well fed on a balanced ration are not nearly as apt to touch dangerous plants as hungry or poorly fed livestock.

3. Do not turn livestock into pasture, particularly woods pastures, until the grazing vegetation has a good start in the spring and do not leave them in pastures too late in the fall when there is little left to eat but fallen leaves, acorns and other dangerous feeds. Many of our most poisonous plants such as water hemlock sprouts, Dutchman's breeches and dwarf larkspur cause trouble mainly in early spring before the grass appears.
4. Consult a competent veterinarian as soon as danger of forage poisoning is suspected.

HOW TO SURVEY A FARM FOR STOCK POISONING PLANTS

Many cases of mineral poisoning are confused with plant poisoning. When livestock poisoning occurs on the farm, particularly when such a diagnosis is made by a veterinarian, a check should first be made on sources of mineral poisoning.

Commonest causes of mineral poisoning are overdoses of salt (about three pounds may prove fatal); paint (licking newly painted surfaces or drinking the water that has accumulated in old paint cans or other receptacles used in paint making); fertilizers (particularly nitrate of soda which may be eaten directly from bags or licked from the outside of bags by salt-hungry animals, or the drinking of water in which old fertilizer bags have been washed); arsenic (especially grazing on grass under trees that have been sprayed with arsenicals or drinking water from receptacles that contained such arsenicals as commercial weed killers); city garbage (which may contain sulfur matches, soap powders or large quantities of coffee grounds) and phosphorus (owing to animals having access to rat and mouse poisons).

If there is no evidence of mineral poisoning, then the search should commence for toxic plants, which should be guided largely by the history of the cases. With the exception of moist alsike or rape which cause skin poisoning, Sudan grass and Johnson grass which cause prussic acid poisoning, and cocklebur sprouts on overflow land, dangerous plants are rarely found in the open pasture. Search first along the fence row for evidence of grazing on wild cherry (particularly the young sprouts on stumps), black locust or ergotized grasses. Then examine the banks of streams or wet places for cocklebur sprouts, water hemlock, sneezeweed, crowfoot or button ball bush. If this proves fruitless, the woods pasture should next receive attention, keeping a sharp lookout for white snakeroot, Dutchman's breeches, larkspur and buckeye. Next in line of search are the waste places where Jimson weed, nightshade and pokeroot showing evidences of grazing may be located.

As a last resort, look to the ornamentals surrounding the house, particularly matrimony vine and castor bean. If this yields nothing of value it is possible that the silage may be at fault although there is little experimental evidence that moldy silage is poisonous. Animals allowed the run of fields containing frozen sorghum or corn stalks, may be affected by a type of poisoning believed to be caused by the formation of prussic acid. During the course of the survey all of the plants discussed in this bulletin should be kept in mind.

SEND SPECIMENS FOR IDENTIFICATION

In case of doubt send specimens of plants suspected of causing trouble to the Purdue University Agricultural Experiment Station, West Lafayette, Indiana. We shall be glad to identify the plants and give such information as we may have regarding their dangerous properties. It will help a great deal if complete specimens, including flowers or fruits and the roots, are sent since this makes identification easier and more accurate. No charge is made for this service.

SPECIES OF STOCK POISONING PLANTS

The species of toxic plants that have been found to be causing greatest damage in Indiana are here arranged in the order of their importance. With few exceptions their dangerous properties have been determined experimentally while their practical importance has been judged as a result of the field work.

WHITE SNAKEROOT. White snakeroot (*Eupatorium urticaefolium*, Reichard) (Fig. 2), found in wooded areas throughout the state, is probably the most important poisonous plant in Indiana, being held responsible for heavy losses of cattle, sheep, goats, horses and mules practically every season. Furthermore, milk sickness in humans may be contracted through

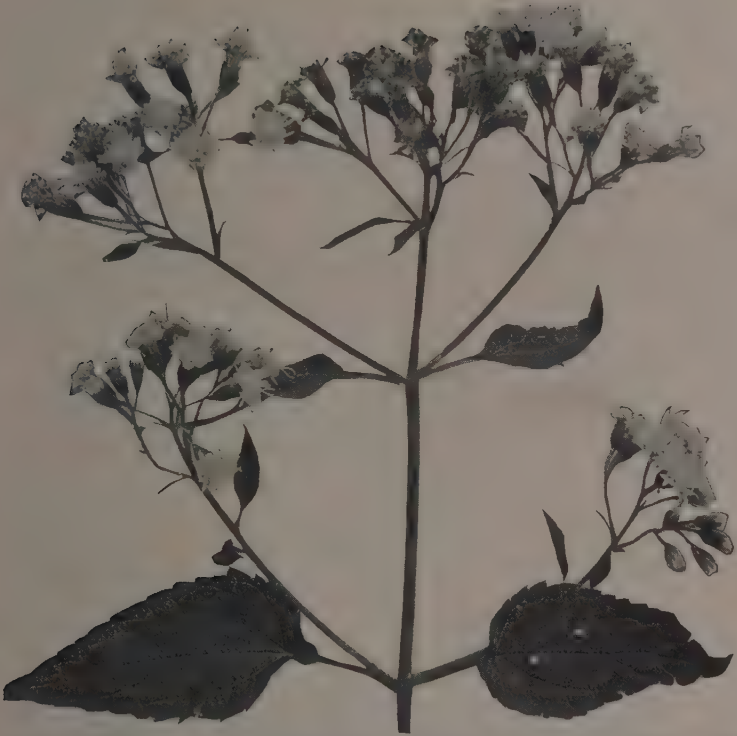

Fig. 2—Flowering top of white snakeroot. Note the clusters of small white flowers and the opposite spear-head shaped leaves each with three prominent veins.

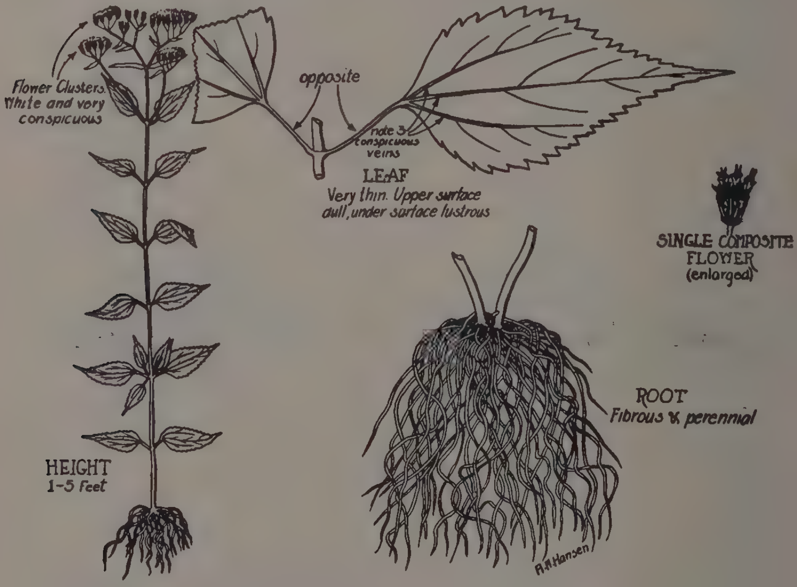
the agency of the milk of cows that have grazed freely on the weed. It has been determined experimentally that the toxic substance, called trematol, enters the milk and may fatally poison suckling calves. Milk sickness is an ancient disease that destroyed many of our pioneers and even today, when woodland grazing of livestock is far less common, we receive reports of loss of human life in Indiana every year from milk sickness. A number of these cases have been investigated by the writer in the field and were found to be genuine cases of milk sickness due primarily to white snakeroot.

The dangerous plant may be recognized (Fig. 3) by the opposite spear-head shaped leaves each with three prominent veins and with under surfaces shiny in contrast to the dull upper surface, by the clusters of tiny bright white flowers that appear during early September, and by the fibrous, matted, perennial roots. The plant grows to an average height of about three feet and it is sometimes cultivated as an ornamental on account of the attractive blossoms.

The most important symptoms of snakeroot poisoning in livestock are periods of severe trembling which are usually preceded by general listlessness, although the characteristic trembling state may be absent in horses and mules. Death from weakness and exhaustion may be lingering or may occur in a few days. Ordinarily the fatal dose for mature cattle and horses is about ten pounds and for mature sheep and goats about three pounds. There is great variation in this respect, however. Hogs are seldom poisoned by white snakeroot unless they graze on the roots.



Flower Clusters White and very conspicuous

Very thin. Upper surface dull, under surface lustrous
SINGLE COMPOSITE FLOWER (enlarged)
ROOT
Fibrous & perennial
HEIGHT
1-5 Feet
R.M. Hansen

Fig. 3—Diagram illustrating the outstanding characteristics of white snakeroot.

The outstanding symptoms of white snakeroot poisoning in man are severe constipation accompanied by frequent vomiting of a greenish fluid, a strong odor of acetone (somewhat resembling sewer gas) on the breath, the occurrence of delirium, and the semblance of fever without a rise in temperature.

The best method of eradicating snakeroot is hand pulling during September when the flowers are conspicuous and preferably following rain when the ground is moist. The pulled plants should be piled and burned or carried out of the woods in a wagon. Where pulling is impracticable, the infested area may be fenced and listed under the Forest Tax Reduction Act with the State Forester, Indianapolis. Although listed land cannot be grazed, the expense of taxes is almost eliminated and the land should eventually yield a lumber income.

WATER HEMLOCK OR POISON PARSNIP. The poisonous principle (*cicutoxin*) in water hemlock (*Cicuta maculata* L.), one of the most dangerous plants in America, is concentrated in the roots and young shoots. Poisoning usually occurs during the spring when sheep, cattle and horses graze on the sprouts (Fig. 4), or during drought when hogs root after the fleshy tubers, although there is evidence that the plant becomes less dangerous as the weather becomes warmer. The roots are also fatal to man, especially children, and a number of human fatalities from this source have been recorded in Indiana. There is also evidence that the dried tops are dangerous when included in wild hay.

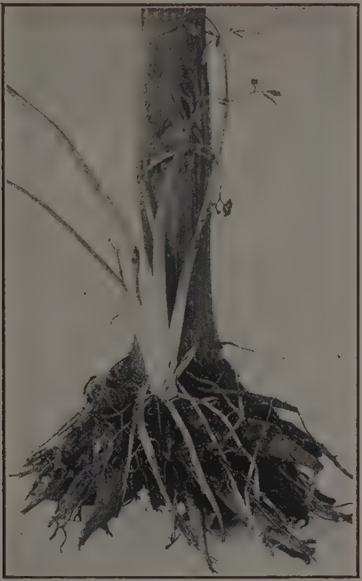

Fig. 4—Both the tubers and the sprouts of water hemlock are highly dangerous to grazing animals.

The usual symptoms of poisoning in animals are marked nervousness followed by muscular twitchings that soon develop into severe convulsions, during which the neck may twist oddly and the victim may run in circles until exhaustion terminates in death in from one to twenty hours. In man the first symptom is nausea followed by dizziness, abdominal pains and severe convulsions. The pupils dilate, the pulse weakens, vomiting (often of a greenish froth) occurs and death ensues from weakness and pain.

TUBEROUS ROOTS
HEIGHT 3-6 Feet
A.H. Hansen

Fig. 5—Diagram illustrating the outstanding characteristics of water hemlock.

Water hemlock is practically limited to moist places, particularly along ditches, streams, lakes and wet roadsides and in marshes. The plant is frequently confused with the harmless, yellow-flowered wild parsnip from which it can be distinguished by the white, lacelike blossoms, the purplish stems and especially by the cluster of tuberous roots (Fig. 5) that resemble small sweet potatoes. When a tuber is cut it exudes a glistening yellow juice containing the poisonous principle. Both the odor and the sweetish taste of the roots are pleasant.

Water hemlock may be destroyed by grubbing but the tubers should not be allowed to lie around since they may cause fatalities even after drying.

WILD CHERRY. A common cause of livestock losses that is seldom suspected by farmers is due to grazing on the young sprouts and the foliage, particularly when wilted, of common wild cherry (Prunus spp., particularly *P. serotina* Ehrh.), a species frequently found in woods and fencerows throughout the state. Both the wild and the cultivated cherry are dangerous, although the wild species are most poisonous. Over a hundred cases of cherry poisoning have been investigated during the five years prior to 1929 in Indiana.

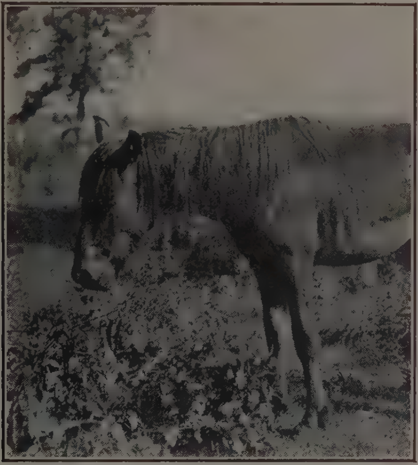

Fig. 6—An advanced case of cherry poisoning in Hancock county. The animal died six hours after the picture was taken. Note the depressed appearance.

The trouble is due to the formation of prussic or hydrocyanic acid, one of the most powerful and rapid acting of plant poisons. In the pure state this is a clear, colorless liquid with the odor of crushed peach kernels. It does not usually occur in the free state in plants but rather in combination with organic compounds, principally sugars, under the chemical designation of glucosides and the prussic acid is released by the action of an enzyme. Poisoning usually occurs when animals graze on the sprouts that arise after cherry trees are cut in a fence-row, when cherry limbs are cast into the pasture by storms or telephone linemen trimming trees that interfere with wires, or when animals graze on cut-over land containing cherry sprouts or in wooded areas containing scrub cherry trees, particularly during the early spring.

The usual symptoms (Fig. 6) are staggering, difficult breathing, dilation of the eyes, convulsions and falling, followed by coma and death. As small a quantity as one pound of foliage may prove fatal. There is evidence to support the use of corn syrup and milk as an antidote for cherry poisoning, although the toxic effect may be so rapid as to render remedies useless.

COCKLEBUR. Young cockleburs (Xanthium spp.) in the two-leaf or cotyledonary stage (Fig. 7) are fatally poisonous to sheep, hogs (Fig. 1) and cattle. In the poisonous condition the two leaves are long and narrow, having no resemblance to the leaves of a mature cocklebur, and consequently the sprouts are frequently unrecognized. It is unfortunate that the poisonous succulent growth is the only stage in which cockleburs are ordinarily eaten by livestock. The toxic principle appears to be in the seeds and is transferred to the pair of temporary leaves.

The usual symptoms produced by cocklebur sprout poisoning are depression, nausea, in some cases frequent vomiting,

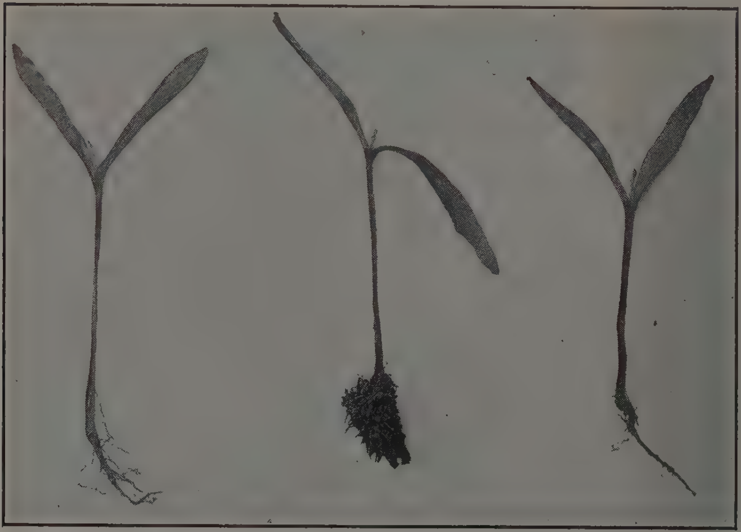

Fig. 7—Cocklebur sprouts in the dangerous two-leaf or cotyledonary stage.

weakness, unsteady gait, twisting of the neck muscles, labored respiration, rapid and weak pulse preceding death which usually takes place in from 12 to 24 hours after the first symptoms are noted. Internally there is congestion of the lungs and stomach lining with an accumulation of a yellowish fluid in the abdominal cavity.

Poisoning usually occurs when wet land, such as overflow land in the spring or land made wet by spring rains, begins to dry since it is then that the dangerous sprouts may appear by the thousands. Most cases of cocklebur sprout poisoning take place during the spring, although fatalities may occur throughout the growing season, particularly when livestock grazes along the banks of streams, ponds or lakes infested with the weed.

The use of fats, oils, whole milk or cream is beneficial and may save poisoned animals if these are administered as soon as trouble is noted. Cockleburs should be destroyed or else grazing animals should be kept away from infested land until the plants are beyond the narrow leaf stage.

The discovery that cocklebur sprouts are fatal to livestock has cleared up the cause of many mysterious losses of livestock, particularly pigs, that occur every spring throughout the state. Cocklebur sprout poisoning has frequently been confused with cholera, hemorrhagic septicaemia and other diseases of livestock.

BLACK LOCUST. The bark and seeds of black locust (*Robinia pseudo-acacia* L.), commonly found in fencerows, along roadsides and similar situations on farms throughout the state, contain a poisonous principle known as *robitin* that is so powerful in action that so small a dose as .0015 gram in a horse and .02 gram in cattle causes a toxic reaction.

Numerous cases of black locust poisoning in Indiana have been investigated, most of which have been caused either by cattle grazing on the sprouts or, more frequently, by horses gnawing the bark while temporarily tied to a locust tree. A few losses among sheep have also been observed as a result of eating the pods.

Dr. D. K. Buzzard, an Indiana veterinarian who has had considerable experience with locust poisoning, describes the symptoms as follows: "In horses, colicky pain with irregular pulse and purging followed by inaction of the bowels, nerv-

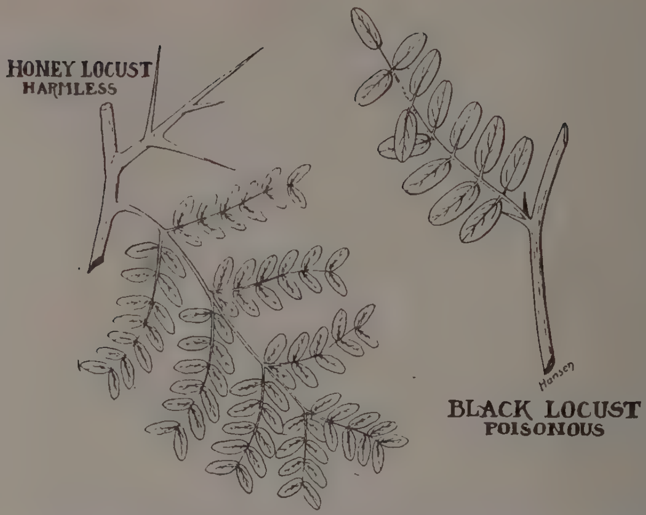

Fig. 8—Note the huge, branched spines and small leaflets of the harmless honey locust in contrast to the small spines and larger leaflets of the poisonous black or common locust.

ous depression and collapse. In cattle the symptoms are colicky pains, constipation, purging, followed by irregular pulse, nervous excitement and vertigo bordering on mania. There is no certain symptom or series of symptoms since locust poisoning may easily be mistaken for other types of poisoning, hence in diagnosis we must rely largely on the history of the case."

Black locust must not be confused with honey locust (Fig. 8) which, although more vicious in appearance due to the large, branched spines, is harmless. The leaves (leaflets) of honey locust are also much smaller than are the leaves of the dangerous black species.

There seems to be considerable variation in the toxic properties of black locust and the exact conditions under which poisoning occurs are not known. Strangely, most reports of locust poisoning do not come from the locust area of the southeastern part of the state where the tree is most commonly found.

The roots and bark of black locust are also poisonous to humans. In one instance thirty-two boys became severely ill from the effects of chewing locust bark.

STAGGERWEEDS. In all parts of Indiana, but principally in the southern highland section spring staggers is a common

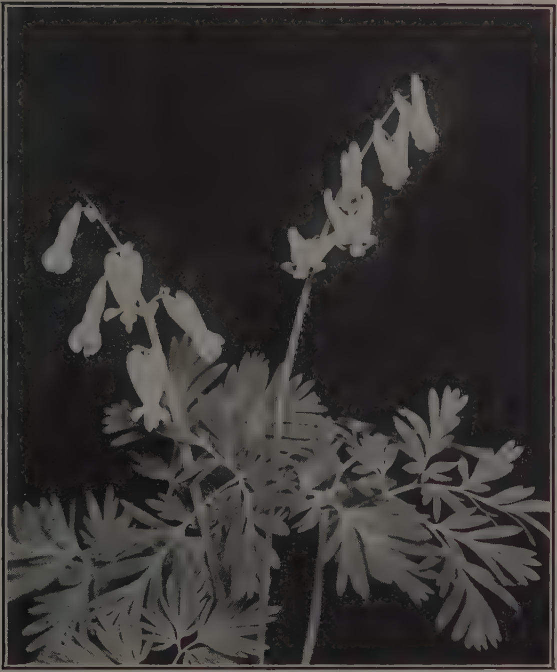

Fig. 9—Both the foliage and the bulbs of Dutchman's breeches (right), a plant distinguished by the two-spurred blossoms, are poisonous to cattle. The plant resembles squirrel corn (left), which is mildly poisonous and possesses heart-shaped flowers.

experience among cattle that have been turned into woodland pastures for early grazing. The trouble is frequently due to grazing on staggerweeds of which there are two species. One, also known as Dutchman's breeches (*Bicuculla cucullaria* [L.] Millsp.) (Fig. 9), is a handsome little wildflower with white, double-spurred blossoms, lace-like foliage and scaly bulbs (Fig. 10), while the other, frequently called dwarf larkspur (*Delphinium tricorne* Michx.), may be recognized by the blue or whitish blossoms, buttercup-like leaves and fleshy, bulbous roots (Fig. 11).

Both species, which frequently grow in company with each other, develop early from the fleshy, underground parts. Neither seems to cause much trouble after mid-May and they rarely poison horses and are apparently harmless to sheep. One Indiana farmer who lost heavily of cattle from Dutchman's breeches poisoning succeeded in practically destroying the pest by grazing heavily with sheep during the early spring.

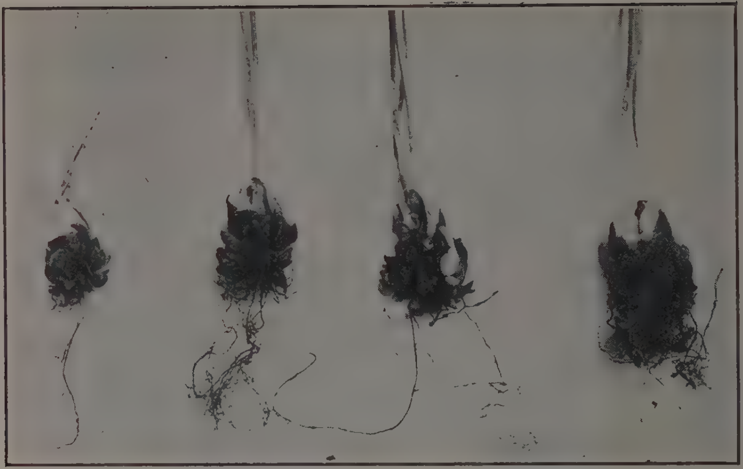

Fig. 10—The poisonous bulbs of Dutchman's breeches or staggerweed.

The poisonous principle in Dutchman's breeches has been isolated and found to be a toxic alkaloid that exists in both bulbs and tops. The toxic properties of dwarf larkspur are similar to those of the well known larkspur of western ranges.

The symptoms produced by the two plants are similar, the outstanding effect being the staggering gait. As one farmer described the effect of Dutchman's breeches on his cattle, "the animals became very weak, staggered and could barely walk.

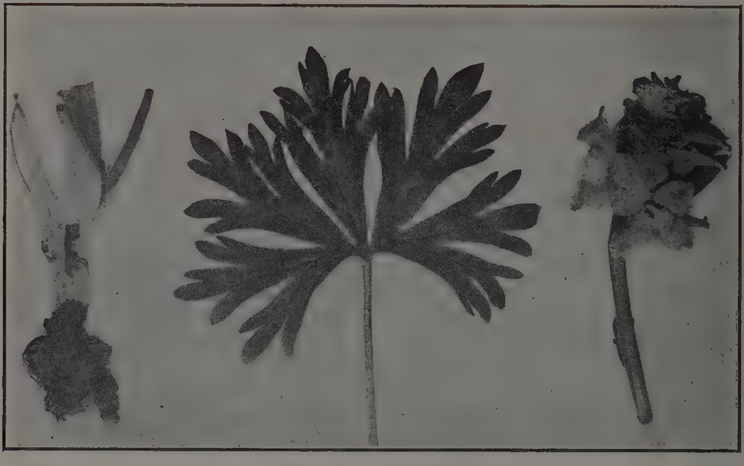

Fig. 11—Bulbs, leaf and flower of dwarf larkspur, a poisonous species found in woodland pastures.

They staggered for a few paces, rested awhile, staggered some more while the eyes became staring and glassy, and the victims gave little milk." In dwarf larkspur poisoning there is a general stiffness of gait, the animals fall and kick convulsively, constipation is severe and breathing difficult. Death usually results a few hours after the first symptoms are noted and is closely followed by bloating.

The best way to prevent staggerweed poisoning is to keep the animals out of the infested woods until after the middle of May. When trouble occurs, remove the livestock immediately, feed dry feed in the barn and consult a veterinarian. Melted lard poured into the throat may also save poisoned animals.

BUCKEYE. Buckeye (*Aesculus glabra* Willd.) sprouts and nuts are fatally poisonous to cattle, sheep and hogs while the nectar of at least one species is deadly to bees when they are compelled to feed on it during periods of shortage of other pasture.

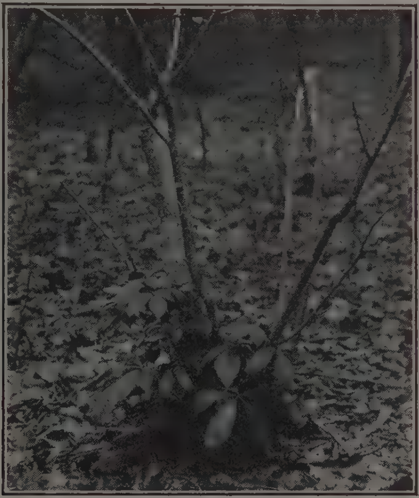

Fig. 12—Grazing on these buckeye sprouts resulted in the death of a cow and the illness of a calf. (Courtesy Dr. G. W. Fant.)

Poisoning of livestock usually results when animals graze on recently cleared land containing buckeye sprouts (Fig. 12), when the nuts are eaten in quantity by cattle grazing in woods containing little other forage, when animals graze on buckeye sprouts in fencerows during drought or other periods of pasture shortage or when livestock strips buckeye buds from small trees during the early spring.

The poisonous principle apparently acts on the nervous system and causes paralysis, incoordination of movement, labored breathing, twitching of the muscles (Fig. 13), dilation of the eye pupils, slobbering and coma preceding death, although the appetite seems to be unimpaired during the progress of the disease. The outstanding characteristic is the staggering gait like the reeling of an intoxicated man.

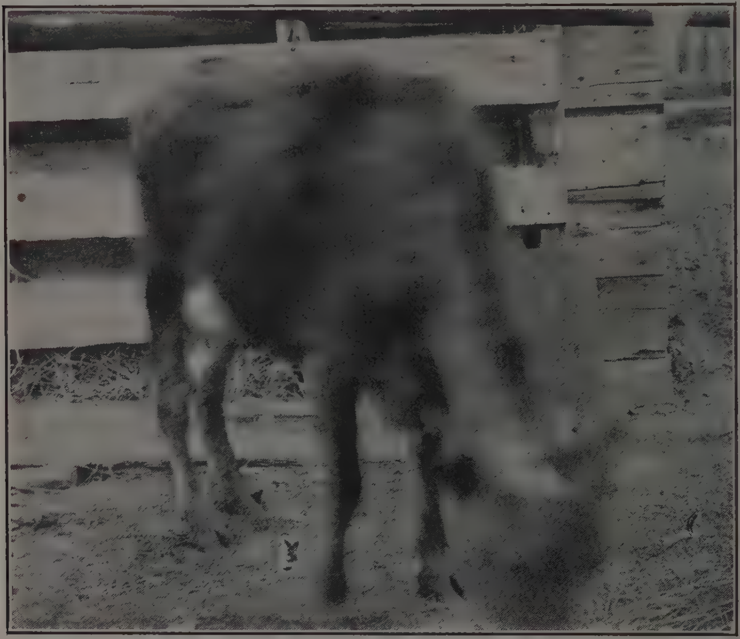

Fig. 13—This picture is not out of focus. The calf is trembling as a result of buckeye poisoning. (Courtesy Dr. G. W. Fant.)

Both the red buckeye (*Aesculus pavia* L.) and the horse chestnut (*Aesculus hippocastanum* L.), common cultivated species, are similar in poisonous action to the native buckeye. Horse chestnut occasionally escapes and becomes established as a wild species in Indiana. It can readily be recognized by the fact that the leaflets occur in groups of seven as compared with five in buckeye. The eating of horse chestnut fruits has been held responsible for death in children.

JIMSON WEED. Common Jimson weed (*Datura stramonium* L.) is poisonous in all its parts, particularly the seeds, the leaves being used in medicine. A number of fatal cases of human poisoning from Jimson weed have been reported, due principally to children eating the fruits or sucking the flowers.

Farm animals ordinarily leave Jimson untouched on account of the repugnant odor and unpleasant taste. Sometimes, however, when other green vegetation is scarce or due possibly to a faulty diet, hogs and cattle eat Jimson with fatal results. Occasionally, also, the young sprouts are eaten in dangerous quantities. Jimson poisoning is usually accompanied by nausea, marked dilation of the pupils of the eyes, excitement, increased pulse and muscular paralysis.

An interesting case of Jimson poisoning was recorded in Parke County, Indiana, where a farmer lost seven cows after the animals had partaken liberally of silage containing large amounts of Jimson weed. On another farm two pure bred Holstein cows died under circumstances that pointed toward Jimson sprouts as the cause of the trouble.

DEADLY NIGHTSHADE. Deadly nightshade (*Solanum nigrum* L.) (Fig. 14), sometimes called bittersweet, may be found in pastures, woods and waste places throughout the state. The species has long been regarded as poisonous although the toxicity varies greatly. It is believed by some that musky-odored plants are most dangerous. The poisonous principle, a chemical (glucoside) called *solanin,* is present in the stem and green berries, the mature fruits being apparently harmless and even edible since they have been used without ill effects in the making of pies and tarts. A horticultural variety known as Wonderberry has been developed.

A number of livestock losses have been noted in Indiana, principally among poultry, sheep and hogs, as a result of eating the green parts, usually the unripe berries, of this species. The symptoms ordinarily displayed are weakness, stupor and muscular paralysis preceding death, with convulsions, constipation and nausea sometimes present.

The plant should be mowed in pastures during early bloom, before the berries form. It is an annual, growing from seeds only.

POKEROOT. All parts of common pokeroot (*Phytolacca decandra* L.), particularly the roots and green berries, are poisonous to cattle, sheep, hogs, horses and humans, although the toxic principle is apparently destroyed by boiling since the young leaves are considered excellent as greens.

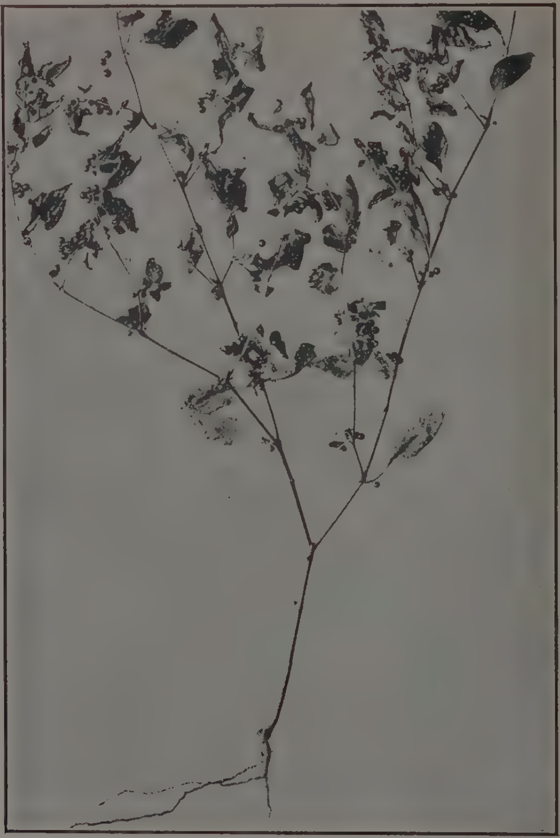

Fig. 14—Black or deadly nightshade. The foliage and green berries are dangerous to livestock.

Most instances of pokeroot poisoning in Indiana among livestock have been confined to hogs, and were due principally to eating the roots. Two human deaths from the eating of pokeroot, one caused by eating the berries and the other by mistaking the roots for parsnips, have also come under our observation.

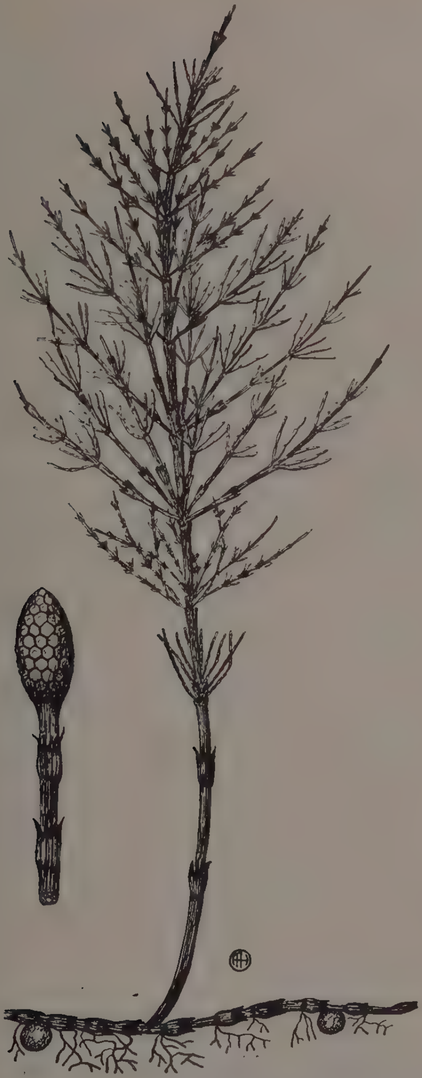

Fig. 15—Horsetail or scouring rush showing the creeping root and the poisonous vegetafive stage. The early spring or cone stage is also illustrated.

POISONOUS PLANTS OF MINOR IMPORTANCE

SCOURING RUSH (*Equisetum arvense* L.). When scouring rush or horsetail (Fig. 15), a species frequently found in barren fields and along railroads, is included in quantity in hay, a fatal disease of horses and sheep called equisetosis may result, although there is no evidence that the green plant is in the least dangerous under Indiana conditions.

Scouring rush poisoning usually appears during the winter, particularly when wild hay is fed, the animals apparently developing a depraved appetite for the plant. The outstanding symptoms are extreme emaciation, muscular weakness, marked nervousness, faulty vision, stiffness of gait, paralysis, coma and death. The appetite seems to be unimpaired during the progress of the trouble. Death may be sudden or lingering, the lungs and kidneys are usually congested, while during the final stages the pulse becomes rapid and weak and the temperature rises. An immediate change of feed to clean hay as soon as evidence of trouble appears usually gives relief.

There are two stages of scouring rush, the early spring growth, which is merely a leafless stem tipped by a cone, and a later development that somewhat resembles a miniature pine tree. Both stages arise from the same creeping root. The name scouring rush alludes to the fact that the late stage was formerly extensively used for scouring pots and pans on account of the high silica content.

MAYAPPLE OR MANDRAKE (*Podophyllum peltatum* L.). Occasional poisoning in cattle, hogs and sheep, particularly during the early spring, occurs as a result of eating the roots and young shoots of common Mayapple, a woodland species containing the poisonous principle *podophyllin*. The fruits and mature tops seem to be quite harmless.

Mayapple is the source of a drug utilized in medicine and there are records of human deaths due to overdoses of this drug. The powdered root is capable of causing severe inflammation of the eyes and deep-seated ulcers resembling venereal sores.

Symptoms of Mayapple poisoning in cattle are profuse salivation, moaning as though in pain, nervous excitement, dilation of the pupils of the eyes, congestion of the mucous membrane, marked diarrhoea, loss of appetite and coldness of the extremities.

The only case of Mayapple poisoning among hogs observed in Indiana occurred on a Daviess County farm where two animals were allowed to graze liberally on the young shoots, the only green vegetation available. Both hogs became ill, trembled slightly and died without signs of suffering. The animals were posted and the stomachs were found to be about half filled with Mayapple shoots.

ERGOT (*Claviceps purpurea* [Fr.] Tul.). Ergot is a fungus disease of rye (Fig. 16), quack grass, bluegrass, redtop and other members of the grass family. The fungus produces hard, blue-black or dark purple bodies (Fig. 17) that apparently replace the seeds and that contain a dangerous drug called *ergotin*. This drug is capable of causing a gangrenous type of livestock poisoning in which the tail, hoofs, and other extremities slough off, a form of disease characterized by severe nervousness, impaired appetite, general loss of condition, delirium and fatal convulsions, or abortion in cows, sows or mares. The trouble occasionally occurs as a result of eating ergotized wild hay.

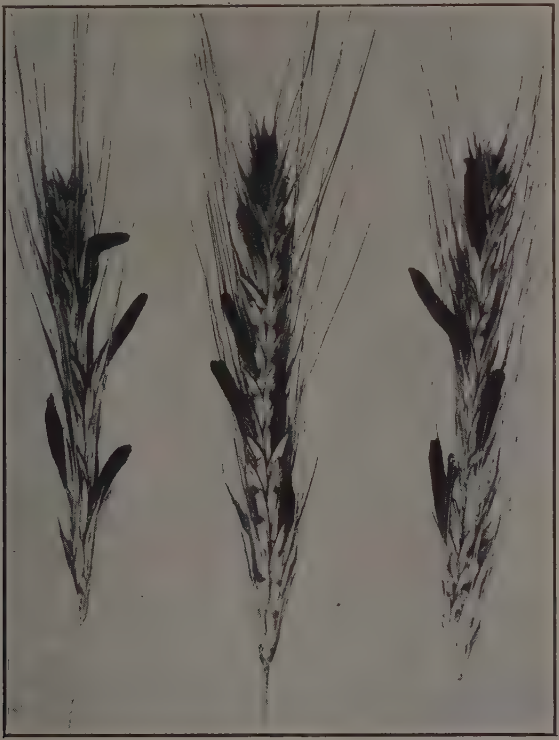

Fig. 16—Ergot infestation on rye is common in Indiana.

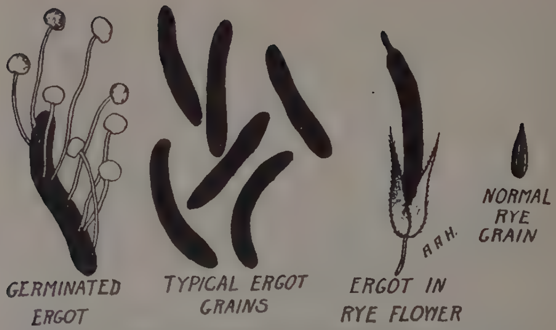

Fig. 17—Ergot on rye. The dark bodies may cause poisoning or abortion in livestock. They occur on members of the grass family only.

Owing in part to improved methods of seed cleaning and possibly to weather conditions unfavorable to the development of the fungus, ergot poisoning and abortion is comparatively rare. In the past, however, severe epidemics of ergotism have occurred in Indiana, influenced greatly by conditions favorable to the spread of the fungus. It is felt that ergot poisoning is a potential rather than an immediate danger influenced largely by conditions. During an epidemic of the gangrenous form of the disease that occurred a number of years ago in Indiana the trouble was at first confused with foot and mouth disease on account of the peculiar effect on the hoofs of infected animals.

RHUBARB (*Rheum rhaponticum* L.). The leaves (not the stalks) of garden rhubarb contain dangerous quantities of oxalates, and a number of human fatalities as a result of eating rhubarb foliage are recited in medical literature. Similar trouble has been observed in livestock as for example on a Shelby County farm where nine hogs died after eating a wheelbarrow full of rhubarb leaves thrown to them as feed. The animals foamed at the mouth, staggered and died in convulsions in from three to four hours after the first symptoms were noted. A post-mortem examination revealed large quantities of rhubarb leaves in the stomach. On a farm near Knightstown a cow died under similar circumstances.

CASTOR BEAN (*Ricinus communis* L.). The common castor bean contains a toxic principle called *ricin* that is concentrated in the seeds. One fatal case of poisoning has been observed in Indiana as a result of a calf grazing on the tops of the plant growing as an ornamental near a house.

WATER LILY (*Nymphaea tuberosa* [Paine] Greene). The breaking of a dam on a Daviess County, Indiana, farm drained a pond containing a heavy growth of water lilies. The plants were freely grazed by four hogs with the result that all became ill and two died. One authority records that the fruits of water lilies are fatal to hogs but in this case the entire plant, particularly the sprouts, seemed to be at fault.

KENTUCKY COFFEE TREE (*Gymnocladus dioica* [L.] Koch.). On a Tipton County farm a number of sheep died after grazing on the fruits and foliage of a coffee tree blown down during a storm.

SNEEZEWEED (*Helenium autumnale* L.). Experiments have demonstrated that sneezeweed, a yellow-blossomed species common in wet situations, is poisonous to horses, mules, sheep and cattle. The flowers seem to contain most of the poison, mature plants being most dangerous. Although it is bitter in flavor and is usually left untouched by livestock, animals occasionally develop a depraved appetite for the plant. The bitter principle affects milk. On a Hancock County farm three cows died under circumstances indicating sneezeweed poisoning, the outstanding symptoms being intoxication and fatal convulsions. Experiments in Mississippi indicate that a pint or two of melted lard poured into the throat gives rapid relief.

BLACK-EYED SUSAN (*Rudbeckia hirta* L.). Although experimental work on the subject is lacking there is abundant field evidence pointing to this common wild and ornamental species as the cause of poisoning in cattle and hogs and a number of cases of this character have been observed in Indiana. In cattle the trouble is characterized by severe digestive disturbance, colic, groaning, and passing of parts of the lining membrane in the feces. In hogs loss of consciousness followed by awakening and walking aimlessly for hours has been observed as a result of grazing on the roots and tops of black-eyed Susan.

WILD INDIGO (*Baptisia leucantha* Torr. and Gray.). A poisonous principle occurs in this species, common along fence-rows, that causes severe diarrhoea and refusal to eat. On a farm near Loogootee four cows died as a result of eating hay contaminated with wild indigo and similar losses have occurred in other parts of the state.

COCKLE (*Agrostemma githago* L.). Feeding tests conducted at the Purdue station have failed to confirm the common belief that grain screenings containing cockle cause fatalities in poultry. The only indication of cockle poisoning observed in Indiana was a doubtful case in which the death of four hogs was thought to be due to eating cockle plants and an examination of the stomach revealed quantities of what was identified as cockle roots.

CURSED CROWFOOT OR BUTTERCUP (*Ranunculus sceleratus* L.). All members of the buttercup genus are acrid and narcotic, causing irritation and inflammation of the digestive tract. Most dangerous is the cursed or celery-leaved species, frequently found in wet soil, which contains the poisonous principle *anemonol*, fatal to horses, cattle, hogs, sheep and man.

PRICKLY ASH (*Xanthoxylum americanum* Mill.). Sheep losses due to grazing on the foliage of prickly ash have been recorded. This usually happens when other forage is scarce.

CAT-TAIL (*Typha latifolia* L.). Fatal poisoning of horses, characterized by stiffness, disinclination to move, profuse perspiration and trembles preceding death, has been observed as a result of grazing freely on cat-tails, common plants of wet places.

WHORLED MILKWEED (*Asclepias verticillata* L.). Although an important problem on the western plains, only one case, an instance in which three calves died as a result of grazing on a solid acre of this species, has been recorded in Indiana. The plant is characterized by whorls of narrow leaves.

WATER PARSNIP (*Sium cicutaefolium* Schrank.). Water parsnip, a species somewhat resembling water hemlock, was held responsible for the death of four hogs on a farm near Oxford, Indiana. The symptoms were not fully recorded since the animals died overnight although frothing at the mouth, trembling, rapid respiration, slow heart action and bloating preceding death were noted. Other losses from this species, principally in hogs and cattle, have been observed in Indiana.

WINTER CRESS (*Barbarea vulgaris* R. Br.). All members of the mustard family are noted digestive irritants, particularly when eaten in quantity. Although not ordinarily dangerous, winter cress eaten in excess may prove fatal. In one interesting Indiana case a horse that had eaten liberally of winter cress from a wagon in which the weed was being hauled from a field exhibited labored breathing, trembling, an awkward, stiffened gait and symptoms of abdominal pains.

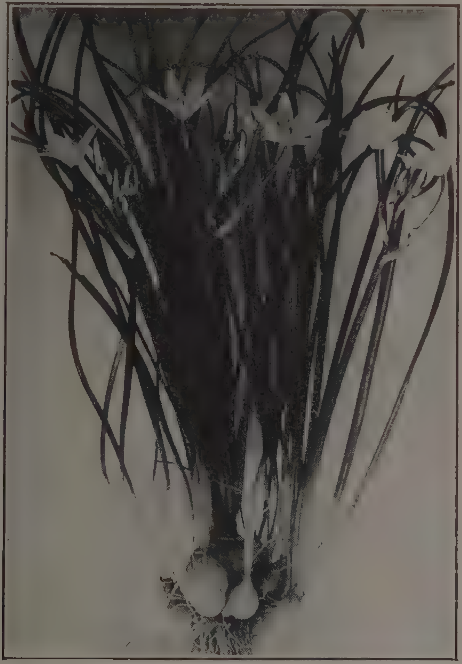

Fig. 18—Star flower, showing the poisonous bulbs. (Courtesy Dr. E. B. Mains.)

GROUNDSEL (Senecio spp.). Illness and death of cows in Indiana has been attributed to grazing on two species of groundsel (*S. plattensis* and *S. Jacobaea*). These plants have been associated with several livestock diseases (pictou cattle disease, Winton disease of horses, Missouri bottom disease).

BUTTON BUSH (*Cephalanthus occidentalis* L.). A toxic chemical called *cephalanthin* occurs in button ball bush, common along streams and in moist places, and illness of livestock due to grazing on the foliage of this species has been observed in Indiana. No fatalities from this cause have been noted.

STAR FLOWER or STAR OF BETHLEHEM (*Ornithogalum umbellatum* L.). The bulbs (Fig. 18) of this common field and lawn weed are poisonous. On a Clark County farm cattle were poisoned by eating the bulbs uprooted by hogs. Grazing animals should be kept out of newly plowed fields on which the bulbs of star flower have been exposed.

RED SORREL (*Rumex acetosella* L.). Red sorrel contains large quantities of oxalate of lime and may cause poisoning in cattle during June and July when the plant is most abundant.

BULL NETTLE (*Solanum carolinense* L.), BITTERSWEET (*S. dulcamara* L.) and MATRIMONY VINE (*Lycium vulgare* Dunal). These members of the potato family are poisonous. A number of instances have been observed in which sheep and cattle turned into abandoned gardens have died as a result of grazing on matrimony vine, an old fashioned ornamental. The usual symptoms are pronounced weakness, staggering, trembles and a high degree of nervousness characterized by twitching of the muscles of the neck and by fatal convulsions.

OAK (Quercus spp.). An exclusive diet of oak leaves has been shown experimentally to be dangerous, sometimes fatally so. A few cases of what appeared to be oak poisoning have been noted on scrub oak land in Jasper County and on cutover oak land in Jackson County, the outstanding symptoms being emaciation, unsteady gait, and the passage of hard, bloody feces. A change of pasture usually brings rapid relief. There is a common but unverified belief among Indiana farmers that the eating of acorns causes a decided decrease in the milk flow, particularly during the fall when acorns are plentiful.

PEACH (*Prunus Persica* Sieb. & Zucc.). Prussic acid, the poisonous principle of wild cherry and sorghum, occasionally develops in peach foliage and losses of livestock have occurred when farm animals grazed on peach sprouts or peach leaves that have fallen during autumn days. In one unusual case a sow was apparently fatally poisoned as a result of cracking a quantity of peach stones and eating the kernels.

MISCELLANEOUS. Among miscellaneous cases of forage poisoning encountered during the course of the field work may be mentioned the toxic effects of flowering spurge (*Euphorbia corallata* L.), bulbous water hemlock (*Cicuta bulbifera* L.), blue flag (*Iris versicolor* L.) and lobelia (*Lobelia syphilitica*

L.) on cattle; swamp milkweed (*Asclepias incarnata* L.) on sheep; wilted apple leaves (*Pyrus malus* L.) on a mule, and the roots of elder (*Sambucus canadensis* L.) on hogs.

CULTIVATED PLANTS THAT ARE DANGEROUS UNDER CERTAIN CONDITIONS

A few of our cultivated plants that are not ordinarily harmful become dangerous under certain conditions. Principal among these are sweet clover, sorghum, Sudan grass, alsike clover and rape.

Sweet Clover (*Melilotus alba* Desr.). With the increased popularity of sweet clover (Fig. 19) and its frequent use for

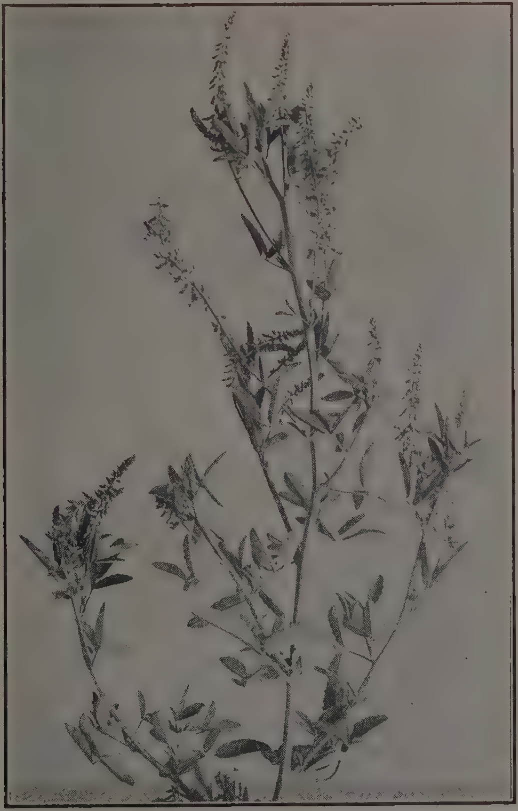

Fig. 19—Sweet clover is excellent for grazing or soil building, but when fed in quantity as hay may cause trouble.

hay, although primarily a pasture and soil improvement crop, a disease new to veterinary science has appeared in cattle and sheep. This disease is characterized principally by the loss of clotting power of the blood. The cause is unknown although the trouble is usually attributed to molds that develop in sweet clover hay. It apparently affects the milk since the disease may be contracted by suckling offspring through the agency of the milk.

Losses usually occur during the winter months, from January on, among animals that have been fed sweet clover hay or silage. The first indication of trouble may be bleeding of the nose. A stiff, jerky gait develops and peculiar swellings appear on all parts of the body but principally along the flanks, backs and sides. These swellings vary from the size of a pea to that of a cocoanut or larger, and they are filled with blood, consequently are soft and puffy to the touch. The animals go off feed gradually and finally die. The postmortem examination usually reveals internal bleeding with blood masses distributed throughout the body, the blood being thin and of a color resembling port wine. Younger animals seem to be most susceptible. The disease is caused only by the second year cutting of hay, a fact which may be due to the finer character of the first season growth since there are indications that the trouble is associated with the coarser growth of sweet clover.

On account of the strange effect of sweet clover on the blood no surgical operations should be performed on animals being fed sweet clover hay or silage. Several instances of fatal bleeding following dehorning or castration have occurred in Indiana. Although there seems to be little, if any, danger of harmful effects of sweet clover as pasture, nevertheless it is safer to remove the animals from such pasture at least a month before any surgical operations are performed.

In the case of valuable animals suffering from sweet clover poisoning it is often possible to save life by having a veterinarian make a transfusion of defibrinated blood from a healthy animal.

Trouble can be prevented by alternating the feeding of sweet clover hay or silage with some other feed every two weeks. Decreasing the amount of sweet clover in the ration is also important since the bad effect is evidently cumulative and no trouble has been noted in Indiana where sweet clover has been fed in moderate quantities. It has also been found that tame rabbits are very susceptible to the effects of sweet clover, exhibiting symptoms long before cattle contract the disease. For this reason the hay or silage may be fed simultaneously to rabbits and if trouble develops among them it is best to withhold further feeding to livestock since this is proof positive that the hay or silage is in a dangerous condition.

ALSIKE CLOVER (*Trifolium hybridum* L.). Sores and inflammation of white skin areas of farm animals are by no means rare in Indiana. Most of this trouble can be traced to allowing livestock to graze on alsike clover moist with dew or rain (Fig. 20), but occasionally rape (*Brassica napus* L.) or St. John's-wort (Hypericum spp.) may be at fault.

Fig. 20—Sheep and moist alsike clover are a bad combination.

Alsike or dew poisoning is not well understood but it seems to be confined entirely to the white skin areas of cattle, sheep, hogs, mules and horses and is most severe when hot sunshine strikes animals that have grazed on moist alsike. An excellent description of the trouble is given by Dr. H. A. Smith, veterinarian of Anderson, Indiana. He states, "Each year I have been called to see animals, usually horses, that show evidence of alsike poisoning. Ordinarily they refuse to eat, there is profuse drooling of saliva and swelling of the tongue, lips or side of the face, especially if the face is marked with white hairs. Then we get cases where a white foot suddenly swells and the horse begins to stamp and even bite at the painful area, which is swollen and hot, exuding a yellow serum. Later the white area may slough out, leaving a bald scar." In sheep there is usually swelling of the face, particularly of the eyes, ears, nose and mouth, followed by peeling of the affected parts.

Occasionally trouble of this character is due to allowing the animals to graze on rape. St. John's-wort (Fig. 21), a yellow-flowered weed sometimes found abundantly in poor-land pastures, may also cause skin poisoning of a similar nature in which the white skin areas of cattle may peel in sheets, the dark areas remaining unaffected. The poisonous principle is here believed to be the oil that may be seen in glands when a leaf of the plant is held toward sunlight.

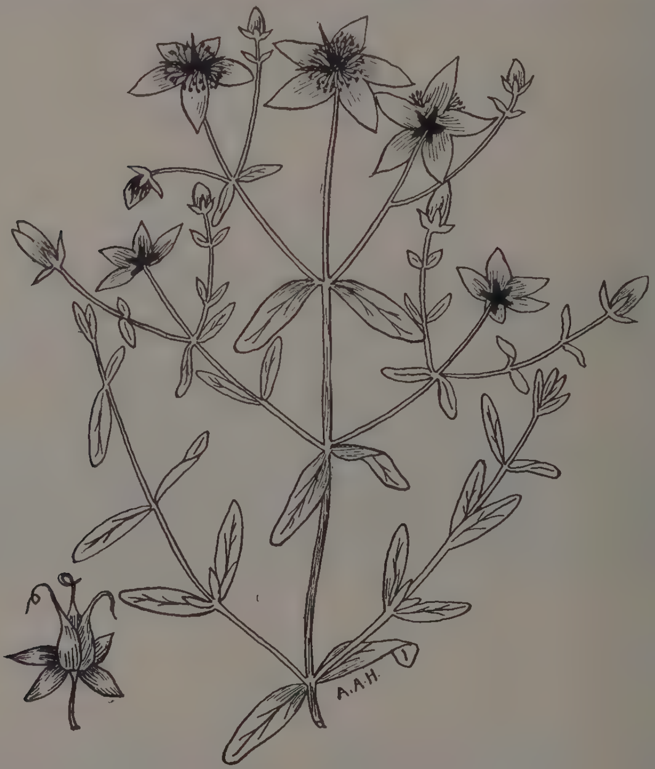

Fig. 21—St. John's-wort, a cause of skin poisoning in run-down pastures. The flowers are bright yellow.

Whether skin poisoning of this type is internal or external in origin is not known. As soon as trouble becomes apparent, an immediate change of pasture will bring quick relief. Unless this is done the result may be fatal.

SORGHUM (*Holcus sorghum* L.), SUDAN GRASS (*H. sudanensis* Bailey), and JOHNSON GRASS (*H. halepensis* L.). When the growth of sorghum, Sudan grass (Fig. 22) or Johnson grass is stunted by frost injury or drought, a poisonous principle known as prussic acid (the same as is found in wild cherry), develops in fatal quantities. Most cases of poisoning of this type in Indiana are due to allowing animals to graze on the second growth of sorghum, particularly when it is withered by frost. The poison, however, disappears on drying so there is no danger when the plants are cured for hay.

Fig. 22—Sudan grass, which in common with Sorghum and Johnson grass becomes poisonous when wilted or frosted.

Sudan grass is a very minor crop in Indiana while Johnson grass is established as a weed in the southern part of the state.

In the southern states Johnson grass, although recognized as a serious weed, is sometimes cultivated for hay and pasture.

The symptoms are similar to wild cherry poisoning. Some observers state that the odor of prussic acid, which is similar to that of burnt almonds, can be detected on the breath of poisoned animals. Death may be very rapid or lingering.

POTATO (*Solanum tuberosum* L.). When either the tubers or the sprouts (Fig. 23) of the common Irish potato turn green after exposure to sunlight the poisonous principle *solanin* develops in quantities sometimes fatal to horses, hogs and other livestock and even to humans. Poisoning usually results from eating young greened tubers or old sprouted potatoes. In one instance a Madison County farmer lost two yearling heifers after they grazed on about a bushel of spoiled, discarded potatoes. In another case the death of a horse was attributed to eating exposed potatoes that had been overlooked following digging. On a farm near Lamar thirty chickens died from the effects of eating greened potato sprouts fed during February.

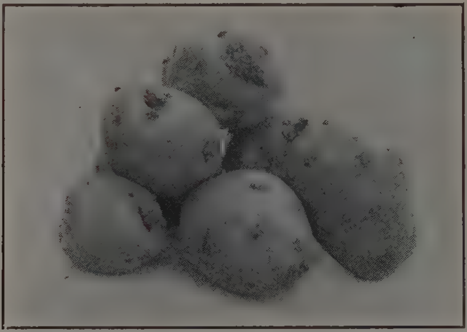

Fig. 23—Green potato sprouts contain the dangerous poison solanin.

MECHANICAL PLANT INJURIES

HAIRBALLS or PHYTOBEZOARS. Hairballs of plant origin are usually caused by the coalescing of plant hairs into spheres (Fig. 24) in the stomachs of grazing animals. Occasionally these hairballs drop into the intestines, causing stoppage that results in a particularly distressing and painful form of death.

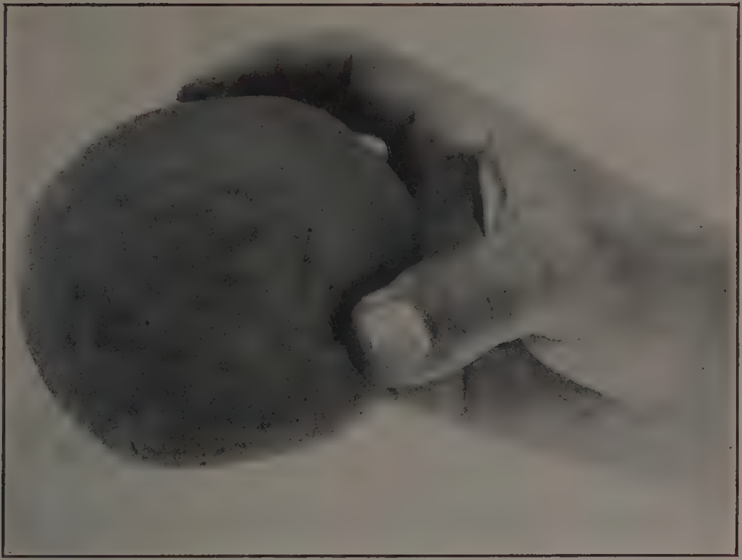

Fig. 24—Crimson clover hairball removed from the stomach of a horse.

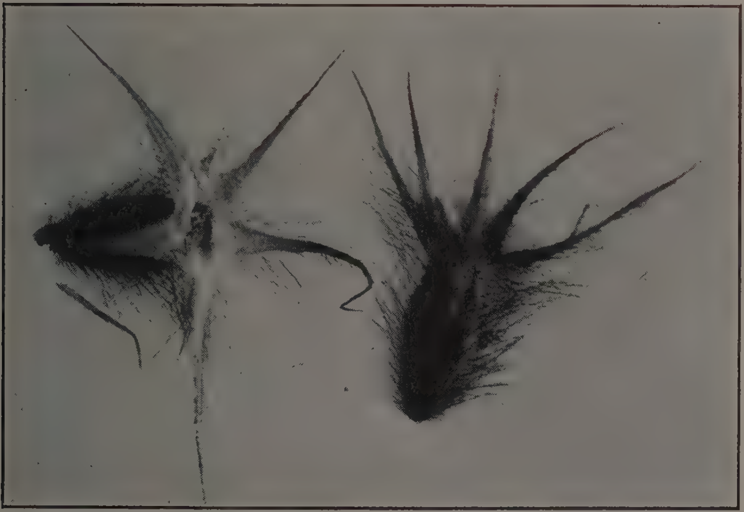

Fig. 25—Enlarged view of the calyces of crimson clover showing the hairs that form hairballs in the stomachs of animals.

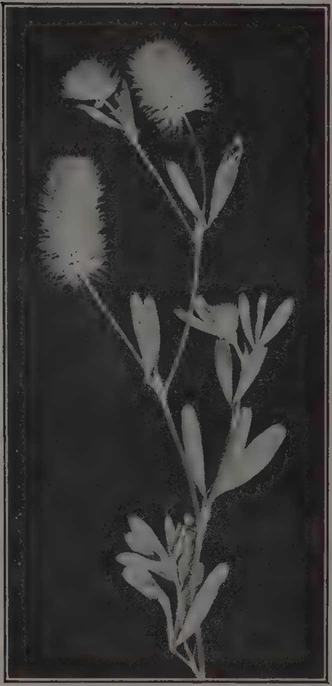

Fig. 26—Rabbit-foot clover, the fuzzy heads of which may cause the formation of hairballs in the stomachs of grazing animals. Common in run-down pastures.

Livestock losses of this character have been recorded in Indiana from flowering crimson clover, where the trouble is due to the hairs on the calyces (Fig. 25), and to over-ripe rye. Any plant equipped with barbed hairs or beards, such as millet, oats, barley, wheat, rabbit-foot clover (Fig. 26) and cocklebur, may cause trouble of this character. Losses from hairball formation are frequently diagnosed incorrectly since the true cause of the trouble cannot be ascertained unless post-mortem examination of the animals is made. When horses are allowed to eat liberally of barley the beards sometimes form spheres under the tongue that cannot be dislodged without assistance such as may be rendered by a veterinarian.

Masses of cockleburs and sandburs may also clog the digestive tracts of grazing animals and cause serious internal injury. The death of a colt on a farm near Bentonville was found to be due to irritation and inflammation of the stomach wall by masses of cockleburs. Poultry losses due to the lodgement of cockleburs and burdock burs in the throat are not rare.

IMPACTION. Common causes of impaction of the digestive tract, some of which have been noted in Indiana, include the woody stems of big English clover, the vegetative stage of horsetail or scouring rush (Equisetum sp.), and corn stalks and rye straw fed without sufficient water.

BARBED BEARDS AND HAIRS. When the beards or awns of wheat, barley, squirrel tail grass (*Hordeum jubatum* L.) (Fig. 27), and other grasses are examined under the microscope tiny barbs are disclosed that somewhat resemble the barbs on fish hooks. When grasses of this character become ripe and brittle in hay the beards break into sections during mastication that penetrate the mouth parts and the lining of the digestive tract and cause serious inflammation. They may also enter the eye, causing blindness. Hide injuries of this nature may also occur. On one Indiana farm four horses died as a

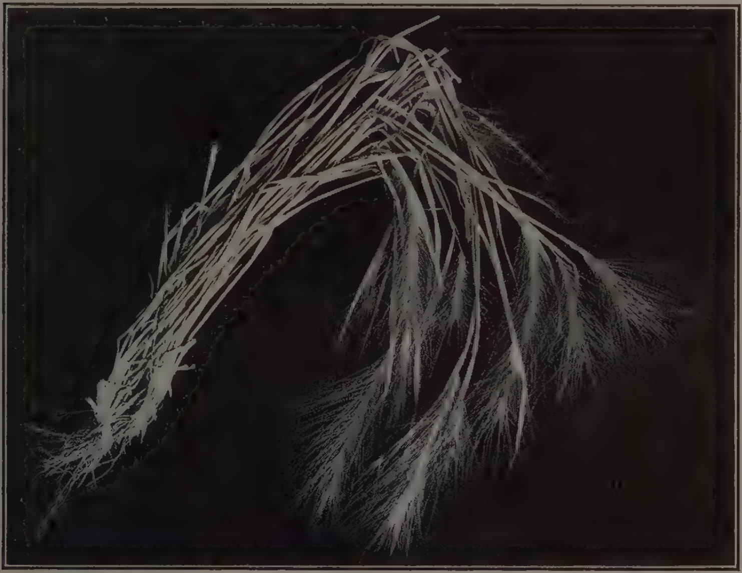

Fig. 27—Squirrel tail grass showing the beards that may penetrate the mouth parts and lining of the digestive tract, causing fatal inflammation.

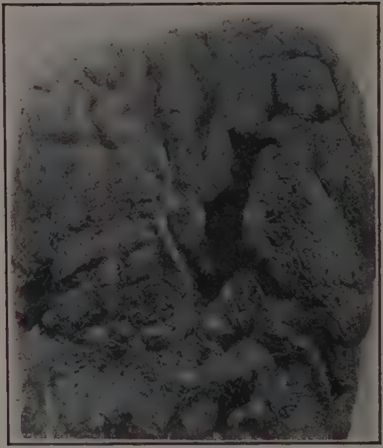

Fig. 28—Swollen tongue of a horse that died from the effects of eating over-ripe squirrel tail grass. Note the penetrating beard sections. Photograph by Dr. R. A. Craig.

result of the penetration of the mouth parts by beard sections of a squirrel tail grass included in the hay. The tongues became so swollen (Fig. 28) that swallowing was impossible and death by starvation resulted.

BURS and SPINES. Livestock injuries, particularly to the mouth parts and to the feet of cloven-hoofed animals, have been noted from the spines and burs of such plants as Russian thistle, sandbur, buffalo bur and unicorn plant (Martynia sp.).

SIXTEENTH ANNUAL REPORT OF THE CREAMERY LICENSE DIVISION

T. H. BINNEY

Indiana Dairy Statistics, 1929

Although mergers and consolidations have taken place, and a decrease in amounts of dairy products manufactured was predicted for Indiana in 1929, the trend of the dairy industry has been toward increased manufacture of dairy products. During the past year the pounds of milk or its equivalent, handled by licensed plants, increased 621,848,763 pounds over the previous year. This large increase was mostly due to an increase in manufacture by some of the old plants rather than through new plants which commenced operating during the past year.

At the time of applying for the renewal of licenses, all creameries, milk plants, cheese factories, condenseries, etc., report the amount of butter, milk, cheese, or other dairy products made or sold during the year. With the information given on the application blanks, it is possible to compile accurate statistics concerning the total production of licensed manufacturing plants. The following table is a summary of the reports received from licensed plants for the years indicated.

OUTPUT OF LICENSED PLANTS FOR 1916, 1920, 1924, 1928 and 1929

	1916	1920	1924	1928	1929
Pounds of Butter	33,026,796	42,577,180	53,462,104	60,409,086	62,700.705
Pounds of Milk	55,059,940	155,950,136	257,417,090	452,088,139	537,463,634
Pounds of Cream	5,799,663	12,224,488	25,219,252	65,614,237	36,052,145
Gallons of Ice Cream	2,111,701	4,132,318	4,865,465	4,904,409	5,250,345
Pounds of Cheese	82,667	233,806	574,686	5,107,087	10,126,417
Pounds of Sweetened Condensed Milk	1,619,880	6,920,592	8,735,498	12,956,783	3,355,734
Pounds of Evaporated Milk	13,657,248	10,265,791	23,912,054	39,490,607	37,973,360
Pounds of Plain Bulk Condensed Milk	2,774,880	5,977,716	19,065,245	25,789,980	31,102,559

The increase in the amount of butter made is 2,291,619 pounds or 3.8 per cent. Butter is the only product manufactured in licensed plants which, since 1920, has shown an increase each year over the previous year. A total of 537,463,634 pounds of milk and 36,052,145 pounds of cream were sold in licensed plants during the past year. This represents an increase of 18.8 per cent of milk and a decrease of 81.9 per cent of cream in 1929 as compared with 1928. The large decrease in sweet cream may be partly due to the fact that the market on that product was "off" and the cream was made into butter. The amount of ice cream manufactured during the past year shows an increase of 345,936 gallons or 7.0 per cent. Cheese production increased 5,019,330 pounds or 98.2 per cent. Sweetened condensed milk decreased 9,601,049 pounds or 74.1 per cent, evaporated milk decreased 1,517,247 pounds or 3.8 per cent, and plain bulk condensed milk increased 5,312,579 pounds or 20.6 per cent.

An estimate of the total dairy products in the state may be secured by using the above statistics and estimating the amount of dairy products manufactured and sold in the plants which are not licensed.

Amount of Butter, Milk, Ice Cream, Condensed Milk and Cheese Estimated as Produced in Indiana During 1929

Pounds of Creamery Butter	62,700,705
Pounds of Dairy Butter	10,476,000
Pounds of Milk	1,531,459,189
Gallons of Ice Cream	9,359,814
Pounds of Condensed Milk	72,431,653
Pounds of Cheese	10,126,417
Pounds of Cottage Cheese	2,736,358

By taking the amount of milk used in the manufacture of each of the various dairy products the total milk production of the state may be calculated. In making this calculation, it has been necessary to estimate the amount of milk and cream consumed direct, the amount of dairy butter made, the amount of milk fed to calves, and the amount of milk lost on farms and in factories.

Total (Estimated) Milk Production

Creamery butter used	1,316,714,805
Dairy butter used	219,996,000
Milk consumed direct	1,533,160,093
Ice cream used	128,697,443
Cheese used	101,264,170
Condensed milk used	181,079,132
Milk fed to calves	98,980,000
Milk shipped out of state	332,614,488
Losses on farms and in factories	117,375,184
Total	4,029,881,315
Milk shipped in	187,441,289
Total milk production in Indiana	3,842,440,026

Creamery Licenses

Every creamery, shipping station, milk factory, cheese factory, person or agent, firm, company, association or corporation, receiving, buying and paying for milk or cream on the basis of the amount of butterfat contained therein, is required to hold a creamery license. A creamery license is valid for one year unless revoked by the Purdue University Agricultural Experiment Station for a violation of the Law or Rules and Regulations under which the license is granted. Points requiring creamery licenses are well distributed over the entire state, as shown by the accompanying map.

Owing to a slight decline in the number of cream stations being operated during the past year, the total number of creamery licenses issued was 1932 as compared with 1948 for the previous year. The number of licensed plants increased by 10 whereas the cream stations show a decrease of 26 in number.

The following table shows the kind and number of plants licensed during the past year.

CREAMERY LICENSES ISSUED FROM 1923 TO 1929 INCLUSIVE

PLANTS AND STATIONS	Number and Year

Total number of Plants	220	234	243	272	307	334	344
Stations	1,583	1,588	1,618	1,631	1,653	1,614	1,588
Total Licenses Issued	1,803	1,822	1,861	1,903	1,960	1,948	1,932

It will be noted that plants handling whole milk have again increased in number over the previous year. Within six years the number of plants handling milk alone have doubled in number. From present indications the number next year will be even larger.

Milk routes have spread over large portions of the state, causing a shortage of cream, and resulting in a reduction of the number of cream stations being operated. At the present time there are a large number of nonpaying cream stations in the state which will eventually be taken out causing a further reduction in the number. The short time in which stations have operated in some towns during the past year would indicate that the larger companies were experimenting with them to determine whether or not the stations could be operated on a paying basis.

The following table shows the number of plants which reported each of the five products for the years indicated:

NUMBER OF PLANTS REPORTING BUTTER, MILK, ICE CREAM, CHEESE AND CONDENSED MILKS FROM 1923 TO 1929, INCLUSIVE

PRODUCT	Number of Plants Reporting						
	1923	1924	1925	1926	1927	1928	1929
Butter	123	123	125	131	142	140	134
Milk	133	139	154	168	202	221	229
Ice Cream	64	62	67	66	73	74	73
Cheese	4	4	3	3	9	21	21

March-1930

Location of Licensed Plants and Cream Stations for the Year Ending March 31, 1930.

Testers' Licenses and Examinations

All plants or stations which buy milk or cream on a butterfat basis must have in their employ a licensed tester who is responsible for the accuracy of the tests made.

Testers' licenses are issued to operators of the Babcock test who pass an examination given by the Creamery License Division. The examination consists of both laboratory and written work which deals directly with the sampling and testing of both milk and cream. Candidates must receive a grade of seventy per cent to pass the examination. Those who are successful receive a certificate of proficiency which entitles them to secure a tester's license on payment of the regular fee.

Temporary permits were issued to 1007 persons to test during the year ending March 31, 1930. Out of this number 691 appeared for the examination at one of the nine examination points in the state. One hundred forty-four of those who appeared failed to make a passing grade. The number of failures (144) added to the number who failed to appear (316) makes a total of 460 or 45.6 per cent of those who received permits were not eligible to secure a tester's license.

Twenty-five hundred and sixty-two testers' licenses were issued during the past year; a decrease of one hundred and six from the previous years' total of twenty-six hundred and sixty-eight.

Number of Candidates Examined and Testers' Licenses Issued for the Years Ending March 31, 1920, 1924, 1928, 1929 and 1930.

	1920	1924	1928	1929	1930
Number of Individual Examinations	1,339	850	904	781	691
Number of Failures	226	125	290	188	144
Number of Persons Passing Examination	1,113	725	614	593	547
Number of Testers' Licenses Issued	2,371	2,518	2,661	2,668	2,562

The results of the seventy-five examinations which were held at the nine examination points in the state are given in the following table:

RESULTS OF TESTERS' EXAMINATIONS, 1929-1930

PLACE OF EXAMINATION	Number of Examinations	Number of Candidates	Average Grades (Per Cent)		
			All Candidates	Candidates Passed	Candidates Failed
Lafayette	14	169	76.2	83.2	48.7
Muncie	9	83	73.6	80.7	51.3
Fort Wayne	10	70	80.6	83.3	66.2
Plymouth	2	10	81.1	84.6	49.0
New Albany	7	45	75.5	79.5	59.5
Evansville	8	82	72.4	79.0	45.4
Terre Haute	8	69	78.1	81.1	63.9
Indianapolis	9	89	78.7	84.3	53.2
North Vernon	8	74	76.2	82.1	54.2
Totals	75	691	76.3	82.1	54.2

Glassware Inspection

One of the essentials in securing an accurate test of milk or cream is the use of accurate glassware and accurate weights. To insure against the use of inaccurate milk and cream test bottles, milk pipettes, and weights, the law requires that all such pieces be examined for accuracy by the Purdue University Agricultural Experiment Station. When found to be correct they are stamped with the letters "S. G. P.," meaning "Standard Glassware Purdue." Only such glassware that complies with the specifications described in sections seven and twelve, chapter 340, Indiana Statute, Acts of 1913, are examined for accuracy. Indiana Standard Glassware complies with the recommendation of the Official Dairy Instructors' Association and is the type adopted by a majority of the states.

During the past fiscal year 54,612 pieces of Babcock testing glassware were examined by the Glassware Inspector of the Agricultural Experiment Station. In addition 494 nine-gram weights were inspected and all found to be correct. This is 2190 pieces of glassware less, and 226 nine-gram weights more than were inspected last year.

The total per cent of glassware found to be incorrect during the past year was considerably higher than the previous year. While there were no inaccurate pipettes and only one inaccurate milk test bottle, there were thirty more inaccurate cream test bottles than the previous year. One hundred and five incorrect cream test bottles out of a total of 36,954 bottles calibrated appears to be a small number, yet if these bottles were allowed to go into stations or plants where each would be used once a day, the result would be over 32,000 incorrect tests being made during a year.

The following table gives the amount of each kind of glassware inspected, and the number of pieces found to be incorrect:

GLASSWARE INSPECTION

KINDS OF GLASSWARE	Total Number of Pieces	Number Incorrect	Per Cent Incorrect
Cream test bottles	36,954	105	.284
Milk test bottles	13,824	1	.007
Milk pipettes	3,834	0	.000
Summary	54,612	106	.194

Testers' Licenses Revoked

One of the duties of the Creamery License Division is to insure both the producers and manufacturers that accurate weights and tests of milk and cream are being made by operators of the Babcock test. Inspectors of the Division are continually checking cream and milk stations, and factories, to determine the accuracy of testing, weights, and records of milk and cream purchased. When an operator is found manipulating tests, weights, or records, either intentionally or unintentionally, he is warned that such practices is a violation of the Creamery and Testers' License Law. If such violations continue, evidence is obtained by the inspectors, and the operator is asked to appear before the State Creamery Examining Board to show cause why his license should not be revoked.

During the past year the following testers were requested to appear before the Examining Board and after considering the evidence the Board recommended to the Purdue University Agricultural Experiment Station that their testers' licenses be revoked:

Mrs. Hattie Curts, Fredericksburg, Washington County, Indiana; tester for Gray-Von Allmen Sanitary Milk Co., Louisville, Kentucky.

Mr. Owen Stine, Bremen, Marshall County, Indiana, tester for Wakarusa Cooperative Creamery Company, Wakarusa, Indiana.

Mr. Frank Butts, Rossville, Clinton County, Indiana, tester for Swift and Company, Logansport, Indiana.

Mr. Ed. Shemley, Napoleon, Ripley County, Indiana, tester for Napoleon Creamery, Napoleon, Indiana.

Mrs. Pearl Connally, Shelbyville, Shelby County, Indiana, tester for the Wadley Company, Indianapolis, Indiana.

Mrs. Ethel Wilson, Greentown, Howard County, Indiana, tster for Swift and Company, Marion, Indiana.

Miss Carrye Wolpert, Elizabeth, Harrison County, Indiana, tester for Armour Creameries, Louisville, Kentucky.

Miss Elizabeth Kron, Elizabeth, Harrison County, Indiana, tester for Armour Creameries, Louisville, Kentucky.

Mr. James Dougherty, Jasonville, Greene County, Indiana, tester for Armour Creameries, Terre Haute, Indiana.

Mrs. Mary Dean, Hartford City, Blackford County, Indiana, tester for Schlosser Brothers, Fort Wayne, Indiana.

Miss Cora Hubbell, Coal City, Owen County, Indiana, tester for Pioneer Creamery Company, Champaign, Illinois.

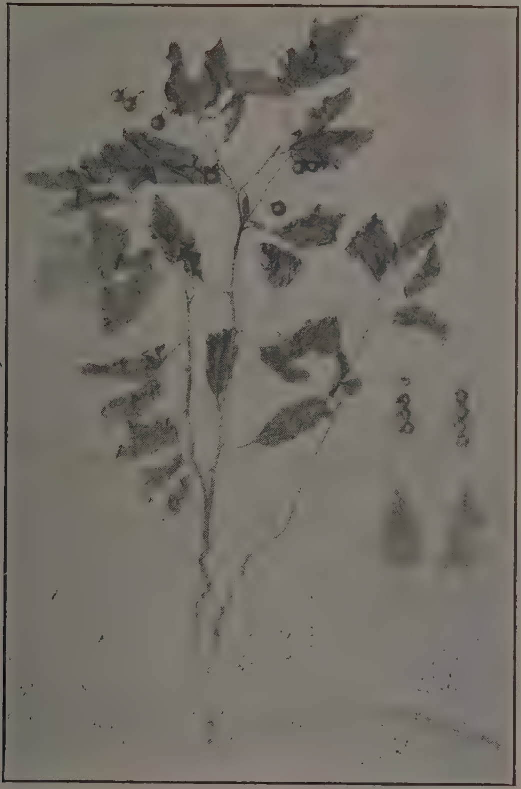
UNIVERSITY OF ARIZONA LIBRARY

ARIZ.UNIV.LIB. APR 17 1931

CIRCULAR No. 177 OCTOBER, 1930

INSPECTION OF AGRICULTURAL SEEDS



Horse nettle. This weed is a perennial that is spreading rapidly in Indiana.

Agricultural Experiment Station
Purdue University
Lafayette, Indiana

This circular contains a report of the Agricultural Seed Inspection for the year ending June 30, 1930. The complete analysis of 1,045 official seed samples is given with full particulars. In addition 2,280 free test samples of seed were tested during the year.

In accordance with a ruling of the State Seed Commissioner, wholesale seedsmen are required to attach at least one state label to each package of seed delivered to the retail seedsman, who, in turn, is required to attach sufficient additional labels to cover the weight of the package.

Since it is impossible to test all seed promptly during the rush season, directions are given for making germination tests at home.

Shipments of seed seriously misbranded were withdrawn from sale and dealers relabeled such seed correctly and made refunds amounting to $260.00.

Dodder is being spread rapidly by the use of dodder infested seed.

Proper use of this publication will enable purchasers to discriminate between seedsmen who handle good seed and those who handle poor seed. Before buying seed farmers are urged to examine Table VI, "The Standing of Seed Distributors," and Table VII, "The Results of Tests on 1,045 Official Samples."

INSPECTION OF AGRICULTURAL SEEDS

H. R. KRAYBILL, State Seed Commissioner

O. S. ROBERTS R. O. BITLER REGINA B. SCHULTE*

EDITH M. PATT PAULINE BALBACH

This report contains the results of the inspection of agricultural seeds for the period from July 1, 1929, to June 30, 1930. The inspectors visited the seed dealers in all sections of the state and collected 1,493 official samples of seed. Complete analyses of these samples were made and reports were sent to the retail dealers as well as to the distributors of the seed. In addition, 2,280 free test samples and 103 Custom House samples were analyzed. The testing of these samples entailed the making of 3,174 purity tests, 14,888 germination tests, 43 examinations and 140 identifications.

The Indiana Seed Law is essentially a correct labeling law. The law does not prevent the sale of poor seed. It merely requires that definite information be placed on the label in order that the purchaser may decide for himself whether he wishes to use good seed or poor seed. In order that the necessary information may be available the law requires that the seed be labeled with official Indiana State Labels showing the minimum percentage of purity and germination and the maximum number of each of the noxious weed seeds per pound. The purpose of the law is to give the purchaser sufficient information to enable him to buy good seed and also to protect the honest and reliable seed dealer and farmer from the practices of the unscrupulous, dishonest and careless seedsman.

RESPONSIBILITIES OF THE WHOLESALE SEEDSMAN

The wholesale seedsman is required to attach at least one Indiana State Label to each package of seed delivered to the retail seedsman.

RESPONSIBILITIES OF THE RETAIL SEEDSMAN

The retail seedsman is required to attach sufficient state labels properly filled out to each package of seed to cover the total weight of the seed before the seed is offered or exposed for sale. These labels can be chosen of such denominations of weight so that they may be removed and attached to a portion of the seed which may be sold from the original package.

---

* In cooperation with the Seed Laboratory, Bureau Plant Industry, U. S. D. A.

It should be remembered that every package of seed of one pound or more when sold for seeding purposes must have attached to it sufficient state labels properly filled out to cover the total weight of the package. It should also be remembered that it is just as much a violation of the state law to offer or expose seed for sale for seeding purposes without tagging to full weight as it is to sell the same without tagging.

RESPONSIBILITIES OF THE PURCHASER

The farmer should examine the official label carefully before purchasing seed and ascertain whether the seed is of the quality he desires. He should insist that all seed which he purchases be tagged properly with official state labels. Attention should be paid to the date of germination on the seed tag. If the germination test was made more than six months before, in many cases it will be well to insist upon a more recent germination test. Table VI gives the standing of the distributors as determined by the 1930 inspection and Table VII shows the results of the analysis of 1,045 official samples. A study of these tables will enable you to determine the quality of seed handled by the various seedsmen and whether the seed which they sold met their guarantee. The seed law is designed to offer you protection but it will not give you that protection unless you make use of the opportunity which the law provides for you.

FARMERS' EXEMPTION

A farmer is exempt from the provisions of the seed law when the seed is grown, sold and delivered by that farmer on his own premises to the purchaser himself. If, however, the seed is advertised for sale by the public press, circular or catalogue or if the seed is delivered by a common carrier, the farmer is considered as a vendor and must comply with the provisions of the act. Seed taken to community sales for sale must be labeled in accordance with the law.

FREE TESTING OF SEEDS

During the past year 2,280 samples of seed were tested free of charge for farmers and seedsmen. The privilege of having these tests made is one of much value to the farmer and the smaller seed dealers who do not have facilities for testing seeds. Not all of the tests requested can be made promptly during the busy season from January to March. For that reason it is important that you send your samples in as early as possible, preferably from September to December.

Satisfactory tests may be made of the larger field seeds at home, leaving the laboratory facilities of the Experiment Station available for the grasses and clovers which are more difficult to analyze.

DIRECTIONS FOR MAKING YOUR OWN GERMINATION TESTS

The seed to be germinated should be mixed thoroughly and the required number of seeds (100 seeds of grains and 200 of clovers and other small seeds) counted out just as they come.

The plate germinator is satisfactory and very simple to operate. Place the seeds to be germinated between two thicknesses of folded blotting paper or cloth (heavy grade of muslin or canton flannel). This should be moistened and placed between ordinary tin or porcelain plates and kept in a warm room where the range in temperature is from approximately 85 degrees during the day to 65 degrees at night. Select a place for the test not too near a window, stove or register.

The time required for germination tests differs with different kinds of seed. Under favorable conditions grass and clover seeds begin to sprout in three or four days. Continue your tests ten days or two weeks.

Examine your tests every two days, making a record of the number of seeds that have sprouted. Also keep the blotting paper or cloth sufficiently moist. The number of seeds which germinate out of the 100 seeds will give the percentage of germination.

DIRECTIONS FOR TAKING OF SAMPLES

1. The minimum weight of seed forwarded for test should be approximately:
    (a) Two ounces (cupful) of grass seed of any kind or of white and alsike clover;
    (b) Five ounces (cupful) of red and crimson clover, alfalfa, millet, flax or seed of like size;
    (c) One pound (pint) of cereals or seed of like size.

2. They may be drawn:
    (a) With seed triers;
    (b) With long stickers;
    (c) By hand, taking approximately equal parts of the sample from at least three different places in the sack, including the top and opposite sides as near the bottom as practicable.

3. Samples should be drawn from each bag when there are not more than five bags in the lot, from every fifth bag when there are more than five bags, but never from less than five bags. Each sample so drawn is combined into one composite sample.

TOLERANCE

Under the most perfect and approved conditions of testing seeds, variations will occur in purity and germination tests. For this reason the Association of Official Seed Analysts has adopted tolerance or allowances for purity and germination tests. Samples of seed with a guarantee within the tolerances are not considered to be seriously misbranded under the provisions of the Indiana Seed Law, but seed dealers will be expected to change the guarantee on the unsold portions to correspond to the analysis found by the Seed Commissioner.

TABLES OF TOLERANCES FOR GERMINATION TESTS

Percentage of Germination	Percentage of Allowable Variation
90 or over	6
80 or over and less than 90	7
70 or over and less than 80	8
60 or over and less than 70	9
50 or over and less than 60	10
40 or over and less than 50	10
30 or over and less than 40	9
20 or over and less than 30	8
10 or over and less than 20	7
0 or over and less than 10	6

TOLERANCE FOR PURITY TEST

In determining the tolerance for purity the sample shall be considered as being made up of two parts: (1) pure seed and (2) everything not pure seed. The tolerance allowed shall be two-tenths of 1 per cent plus 20 per cent of the lesser part. Example: Seed marked 98 per cent pure, the lesser part is 100 minus 98, or 2. Twenty per cent of 2 equals 0.4. Therefore, the tolerance allowed would be 0.2 plus 0.4, or 0.6.

VIOLATION OF THE LAW

It is a violation of the State Seed Law to offer, expose for sale or sell seed without having it tagged to full weight with official labels or to misbrand the seed. During the past year three cases of non-tagging of seed and twenty cases of misbranding were called to the attention of prosecuting attorneys. The cases resulted in fifteen convictions, four held in abeyance, and one not reported by prosecuting attorney to date.

REFUNDS

Several cases of misbranding have been settled by the seedsman replacing the misbranded seed with new lots of seed or by refunding to the purchaser the cost of the seed. The payment of refunds and the exchange of the seed does not cancel the violation, but it does show the seedsman's good intentions and indicates that he is willing to do all that he can to correct the violation. During this year refunds amounting to $260.00 were paid by seedsmen to the consumer.

FILLING OUT OFFICIAL LABEL

Purity

The minimum purity means the percentage of pure seed of the kind and variety given on the official label. Statements of purity, as 97 per cent, including 2 per cent crop seeds, or 95 per cent and 2 per cent crop seeds, will not be permitted. In cases where the seed contains two or more kinds of agricultural seed, each present in excess of 5 per cent, the seed should be labeled with the green colored mixture labels, Style C.

The percentage of purity on the large seeds such as soybeans, corn, wheat, vegetable seeds, etc., must be given on the official label the same as on any other seed.

The filling out of the column "per cent of seed" on the mixture labels can be best explained by an example. For instance, if a mixture is composed of 60 per cent Kentucky Blue Grass with a purity of 80 per cent and 40 per cent of Red Top with a purity of 90 per cent, the per cent of Blue Grass should be given as 48 per cent, obtained by taking 80 per cent of 60. The Red Top should be given as 36 per cent, obtained by taking 90 per cent of 40.

Germination

There still appears to be some misunderstanding as to the method of stating the percentage of germination on the official label. The term minimum germination means the percentage of sprouts obtained in the prescribed time for the test. If the seed contains hard seeds this percentage should be stated after the term "hard seed" on the official label. In no case should the sum of the percentage of sprouts and hard seeds be given as percentage of minimum germination.

Distributors should not ship seed until the germination test is completed. The statement "In Test" on the official label does not meet the provisions of the seed law. Further, if there is a demand for the seed the dealer may be tempted to sell the seed before he receives a report on the germination, thus placing himself liable to prosecution.

Noxious Weed Seeds

The number per pound of each of the noxious weed seeds present must be listed on the reverse side of the tag irrespective of the number present. The term "trace" is not permissible. The statement of the noxious weeds in terms of per cent or in terms of proportion will not be permitted.

Place Where Grown

The official tag must give the name of the state, territory or foreign country where the seed was grown. Terms such as Domestic, U. S. A., Northwestern and Central States do not meet the requirements of the law, and seed found so labeled will be immediately removed from sale until the tags have been corrected.

DODDER

Dodder is the most dangerous weed that infests clover and alfalfa and may destroy the entire value of the crop for seed and injures it for hay. This weed is spreading rapidly in Indiana, and unless prompt steps are taken to stop its spread it will seriously interfere with our clover seed production.

It is a twining parasite that usually appears in clover and alfalfa in the form of yellowish colored patches scattered over the field. The seeds, which are produced in abundance, are somewhat grayish or yellowish brown, spherical in shape, and can be readily distinguished from clover and alfalfa seed by their dull roughened seed coat. The seed produces a tiny leafless twisting plant resembling a thin tooth pick. As it twists it comes in contact with the growing alfalfa or clover, immediately loses its hold on the ground and attaches itself to its new support by suckers, through which it sucks out the life juices from its new host.

While dodder is usually introduced on the farm by the use of impure seed, it can also be introduced by the use of dodder infested hay, manure and flood water. Dodder seed may remain viable in the soil for five years or longer and a favorable growing season will cause the seed to germinate.

Small infested patches of dodder should be either mowed and removed from the field before the dodder matures seed or burned in the field. If seed has been formed burning is the only safe method of eradication. If the infestation is so great that patch treatment is impracticable the crop may be plowed under or utilized for hay before the seed has formed. Since corn, soybeans, cowpeas, oats, wheat and rye are not susceptible to injury by dodder, a rotation consisting of these crops should be used after an infestation of the soil with dodder seed.

Certified, Verified and Affidavit Seed

Certified seed is seed whose purity, germination and variety is certified to by some state certifying agency or an agency closely associated with some state office or department. The seed is shipped in sealed sacks with a certified seed tag attached. During the growing season the fields are inspected to ascertain trueness to variety of crop, and after the harvest the seed is tested to determine whether it meets the prescribed standards of the certifying agency. In Indiana the Indiana Corn Growers' Association certifies corn, wheat and soybeans. The other most commonly certified seed found in the state is Grimm Alfalfa.

Verified-Origin seed is seed whose origin is attested to by certain government approved seed dealers. Seed verification service deals with origin only, meaning Place Where Grown, and gives no guarantee as to the variety, purity or viability of the seed. At the present time red clover and alfalfa are the only seeds verified as to origin. Verified seed is tagged with tags bearing the official verification emblem.

Affidavit Grimm is alfalfa seed for which the grower has made affidavit as to its being Grimm Alfalfa. This affidavit seed is not regulated by either State or Federal Government.

Summary of 1930 Inspection

The seed samples secured during 1930 were of better quality and more closely met their guarantee than those of any previous year of seed inspection. However an examination of Table III shows clearly that a large part of the seed sold could be greatly improved by proper cleaning.

The percentage of samples seriously misbranded in 1930 was only half of that of the previous year. With the exception of a few, the seedsmen are showing an increased interest and desire to cooperate with the department in the enforcement of the seed law.

Tables IV and V show the percentages of official samples of red clover, alfalfa, sweet clover, alsike clover and timothy having various noxious weed seeds. The most noticeable fact is that the percentage of red clover showing the presence of dodder is increasing greatly. Last year 28.46 per cent of the red clover samples showed the presence of dodder. This is one of the worst noxious weeds in Indiana and farmers should be careful to purchase seed free from dodder seed.

TABLE I.—AVERAGE ANALYSIS OF SAMPLES IN 1922 SEED INSPECTION

	Number of Samples	Purity per cent	Inert Matter per cent	Germ. per cent	Hard Seeds per cent	Number Weed Seeds per Pound	No. Noxious Weed Seeds per Pound

CIRCULAR NO. 178 JANUARY, 1931

EUROPEAN CORN BORER CONTROL–PROGRESS REPORT

1931

A corn field in Ontario, Canada, where the borer did untold damage previous to general practice of clean-up control, showing the effects of a heavy infestation. Photographed September 24, 1926. Borers (see inset) become so abundant they completely riddle the stalks, causing them to crumple over.

EUROPEAN CORN BORER MENACES INDIANA'S MOST IMPORTANT CROP

H. J. Reed, Assistant Director
Agricultural Experiment Station

Indiana farmers grow annually about 4,350,000 acres of corn which has an approximate value of $100,000,000.00, ranging from $75,000,000.00 to $125,000,000.00 depending upon yield and price. This crop forms the basis for most types of farming in Indiana. The place that the livestock and dairy industries occupy in the production of new wealth and the maintenance of soil fertility is dependent upon the successful production of a satisfactory corn crop. In 1926, the farmers of the state were much disturbed when they learned that the European Corn Borer had been found in a few areas in the northeast corner of our state. This insect has been pronounced by eminent agricultural authorities as "the most serious menace that has ever confronted American agriculture." It has caused large losses in New England, and several counties in the corn producing areas of Ontario, Canada. The insect is thought to have been brought to Ontario, Canada about 1910 and before it was discovered in 1920, it had spread over nearly 3,000 square miles, advancing at the average annual rate of about 40 miles. In 1921, the European corn borer was discovered in Michigan in a few townships and it is reported by the Michigan authorities that some farmers in Monroe and Lenawee counties suffered losses of 50 to 70 per cent of their crop last year. The fact that the entire corn crop in Kent and Essex counties, Ontario, was practically ruined in 1925, 1926, and 1927, fifteen years after its introduction, demonstrates the potential destructiveness of this new invader. In those counties, corn growing and the production of hogs was practically abandoned because the new pest laid waste to the corn fields. The infestation in Indiana has spread from 39 townships in 1926 to 303 townships in 1930. During the season of 1930, the extremely hot and dry weather at the critical stages in the life history of the insect prevented it from making its normal increase during the past year. Unless the federal quarantine and satisfactory methods can be developed which will delay the advance of the corn borer, serious losses to Indiana's most important crop are bound to result. It may be necessary to readjust the cropping system, reduce the acreage of corn, stop the sowing of wheat in corn and plant more legumes and grass.

Obviously, the problem is eight-fold:

(1) Maintaining an effective quarantine until control methods can be worked out.

(2) Fundamental studies including behavior studies of the insect and its life history, and development under Indiana conditions which are essential to successful development of more practical and efficient controls.

(3) The study and development of agronomic and farm management practices and corn varieties under Indiana conditions that will enable the farmers to so control the insect and continue to successfully grow corn.

(4) The development of practical mechanical methods of disposing of the remnant stalks.

(5) The establishment of parasites and natural enemies in the infested areas as rapidly as possible.

(6) Acquainting the farmer with the problem and securing the adoption of known controls even in areas where the borer is scarce.

(7) Placing in the hands of growers new control measures as rapidly as they can be developed.

(8) Development of practical insecticidal controls for sweet corn.

Readjustments in the Types of Farming and the Development of New Systems of Farming Necessary to Meet the Situation

Effort is being made to produce strains of corn that will yield well in the infested territory.

The agronomic experts have as their objective the finding of the best and most practical methods of growing corn under conditions of corn borer infestation. The best way now known is to dispose of all remnants of the late corn crop before May. The success of this depends upon community cooperation. It is hoped that some practices will be developed which will make it possible for each individual to protect his crops from serious damage even though all of his neighbors do not cooperate in combatting the pest.

The work in Indiana has been confined to the northern half of the state because that is the part of the state infested at present. Forty-four varieties of corn have been tested to determine the best ones for use. It has been found that such varieties as M.A.C. Yellow Dent and Clements White Cap Yellow Dent may be planted late enough to escape serious infestation from the borer and yet produce fair yields of corn. Early varieties should be planted at a higher

Effect of Fertilizer in Hastening Development of Late Planted Corn.

This corn was planted late enough to avoid serious corn borer injury, June 16th, and was photographed on July 24th.

The plot on the left was fertilized with 200 pounds of 5-15-5 per acre in the row. The four rows to the right of the middle stake were not fertilized.

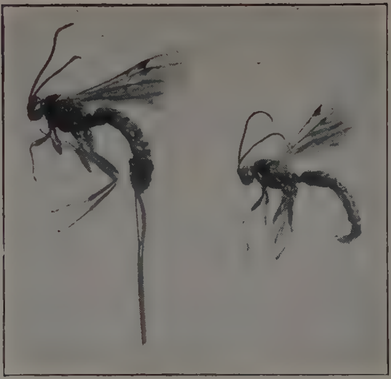
The fertilized corn ripened from 2 to 3 weeks earlier and produced 33 bushels more of merchantable corn per acre than the unfertilized corn. The fertilized corn was 90 per cent mature while the unfertilized corn was only 10 per cent mature when killed by frost.

rate than the later varieties. The use of a phosphate-potash fertilizer applied near the hill or in the row has proven profitable in most of these tests.

Scientific studies are giving new information on the life and habits of the corn borer in this area.

The greater part of our entomological investigations have been conducted at the Federal corn borer station at Monroe, Michigan, where the borers are sufficiently numerous to provide facilities better adapted to entomological studies than were available in Indiana. A Corn Borer Laboratory should be established in this state not later than 1932. Considerable work, however, has been carried on in the state and our workers have been fortunate in securing for liberation in our infested areas a large number of parasites which have been brought in by the United States Department of Agriculture.

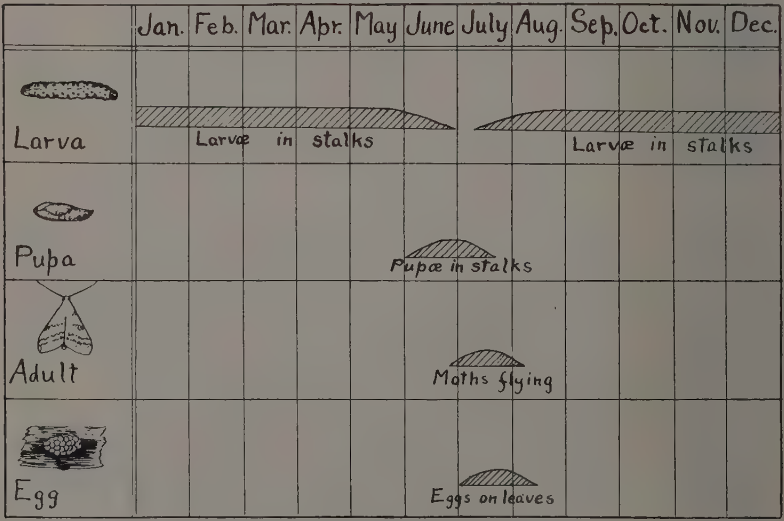
Up to the present time, approximately 166,000 corn borer parasites of 12 species have been liberated in LaGrange, Noble, Allen, Elkhart, Steuben, and Dekalb counties. As the infested area of Indiana is enlarged by the natural spread of the borer and a greater



Several parasites have been introduced from the native home of the borer to assist in checking the corn borer. One species, Exeristes roborator, is shown above. Note the long ovipositor or egg-laying organ of the female on left. With this she can pierce corn stalks and lay her eggs in the burrow with the borer. (After Pettit, Mich. Agr. Expt. Sta.)

supply of host material becomes available for parasitism, the parasite program in the state will be enlarged and additional species introduced.

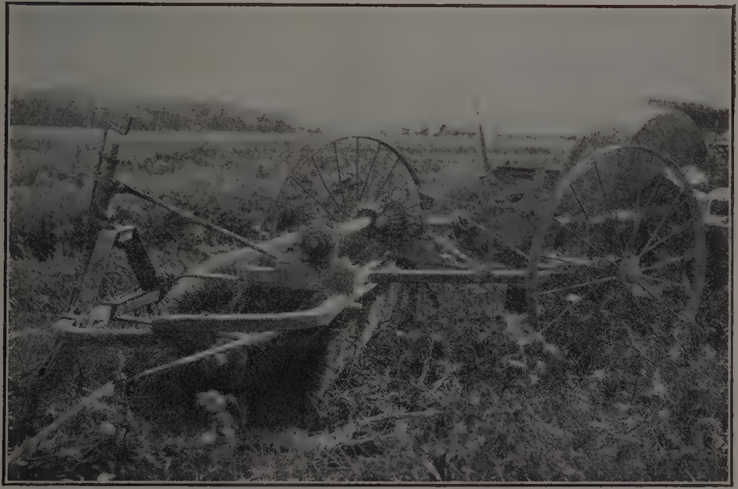
Studies at Auburn, Indiana, show that egg laying begins about June 25 and that the peak of egg deposition is reached about July 7. The status of insecticidal control of the borer is being investigated.



Seasonal history of the European corn borer.

This work should have an important application in the case of sweet corn production as a market and canning crop, and it is anticipated that sweet corn will be the first crop to be seriously affected in a commercial way in Indiana. There are about 50,000 acres of sweet corn grown for canning and market garden purposes which has a value of approximately $1,000,000.00 annually.

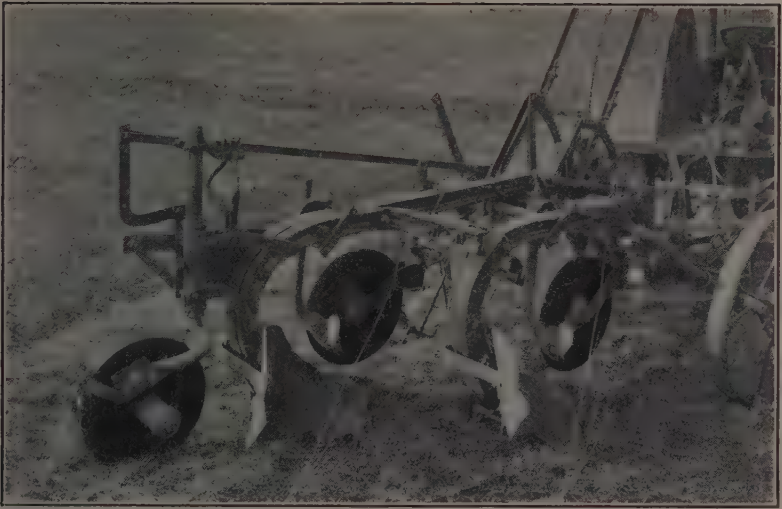
Studies of the planting date of corn in relation to the degree of stalk infestation and borer problems show that there is a proportional decrease in the percentage of stalks infested and the number of borers per stalk if the date of planting is delayed. Corn planted on May 10 showed 100 per cent infestation; corn planted on June 2, approximately 11 per cent infestation and corn planted on June 14 showed no infestation. The best average date for planting corn in northern Indiana is May 10-15. Our problem is, therefore, one of finding and developing new varieties of corn that can be planted later and speeded up by the use of proper fertilizers to mature before frost. No natural host plants other than corn have been observed in Indiana. Considerable effort has been made to discover satisfactory host plants for use as trap crops which would aid in the control of this insect.



An experimental corn stalk sweeper. The transmission permits the quick changing of brush speed for experimental purposes. Designed by Department of Agricultural Engineering to clean fields of corn stalks infested with European corn borer.

A home made adjustable low type sled cutter at work. Note the hand cut stubble in the foreground as compared to those left by the sled cutters.

A corn binder equipped with the low cutting attachment at work in the field. Note that no stubble are visible behind the machine.



A 16-inch gang plow equipped with wires which materially aid in turning under trash. The wires hold the trash against the furrow slice so that it is turned under. The large rolling coulters and separate jointers also aid toward clean plowing.

A 14-inch gang plow equipped with stalk shields and wires for turning under corn stalks. View shows condition of stalks and ground ahead of plow and the type of work being done.

Tests indicate that machinery will play an important role in controlling the corn borer.

From the standpoint of mechanical corn borer control, the greatest problem is to devise a means for handling whole corn stalks left in the field, after hand or machine picking, in such a manner that the ground can be disced and sown to small grain and at the same time obtain fields clean of all remnants or pieces of stalk which permits corn borer control. Several types of machines with power-driven discs have been devised but the field tests have not proved them to be practical for Indiana conditions. Changes are being made on these machines to increase their efficiency. A machine for shaving stalks loose and sweeping them into windrows and cutting fine enough to kill the corn borer is under construction at the present time. Plow tests show the value of large coulters and jointers, together with trash wires and shields which give better than 95 per cent coverage on the average. Much time and effort has been given to the development and improvement of such devices. The use of electric current for killing the young worms has been found impractical for corn borer control. Low cutting attachments for corn binders have proven both practical and effective. The extra labor required to clean up stalks for corn borer control was found to be about $1.30 per acre.

The Quarantine by Federal and State Authorities Should be Maintained.

United States Department of Agriculture and office of State Entomologist have cooperated in this work very efficiently.

Since the discovery of the corn borer in the United States, the Federal Department of Agriculture, State Entomologists and other regulatory officers of the affected states have maintained a quarantine to prevent the carriage of materials likely to be infested from the known infested area to points outside. The quarantine area has gradually extended each year to include new infestations found during the preceding season. The spread of the borer has been held in check except that due to the natural flight of the moth. Inasmuch as the adult is a strong flying moth, the insect is certain to gradually spread to new areas each year until it occurs throughout the corn-growing regions unless practical methods of control can be discovered and, therefore, it is not anticipated that any quarantine will completely prevent spread. However, the quarantine as practiced eliminates to a great degree the possibilities of long distance spread by artificial means. This in turn greatly aids in retarding spread to new regions, and every year of delay offers the research workers additional opportunity to discover more practical and efficient controls as well as new information regarding the life cycle of the insect and the methods for controlling it, when the borer does become a pest of major importance in the corn belt areas. Undoubtedly, the quarantine has prevented long distance spread and has, thus, already saved millions of dollars for the farmers in the corn belt.

Thousands of farmers in the infested district have been reached through meetings, farm visits, and demonstrations.

A program of educational work has been conducted by members of the staff associated with the corn borer work to give our farmers such assistance as they wish in making necessary adjustments in their farming operations to meet the new situation. This work was done in cooperation with the Division of Entomology of the State Conservation Commission.

Many organized tours have been made by our farmers to Ohio, Michigan and Canada to see the great damage to the crops in regions where the corn borer has been at work for a longer period of time and where great commercial damage has occurred. During the last year, 68 farmer meetings have been held with a total attendance of 6,568 people; exhibits have been prepared and displayed at the State Fair and in counties in the corn borer area. Eleven hundred farmers attended low cutting demonstrations.

Fifty-five corn variety and fertilizer demonstrations have been conducted in cooperation with farmers in the corn borer area so that the people of the community could see these results and draw their own conclusions.

In view of the experiences in other states and countries, the European corn borer can easily cause an annual loss of $5,000,000.00 to the Indiana corn crop.

Any research work that will delay the advance of the corn borer and reduce the loss to our agriculture will be a real contribution to the agriculture and general prosperity of the state. When the farmer is prevented from producing new wealth, the State suffers a distinct loss which is felt by bankers, farmers, and most of all, by business men.

The Agricultural Experiment Station would be negligent of its responsibility if it did not clearly and forcibly present these facts to those concerned with the future of our agriculture. The great corn belt of the central west is just ahead of the invader, our research workers are fighting with their backs to the wall and need such assistance and support as can be given by every citizen of the State and those who are the trustees of the funds of the State.

At the request of a number of the agricultural associations of the State, the 1927 State Legislature passed a special act (Acts 1927, Chapter 56), providing funds for research and educational work on the European corn borer and codling moth. This act provided for the necessary assistance, for defraying expenses incurred in conducting experiments, investigations, surveys and educational work, and for the cooperation with the United States Department of Agriculture.

Under the leadership of Professor J. J. Davis, head of the Department of Entomology, G. A. Ficht has been located in the Federal Laboratory at Monroe, Michigan, since April, 1927, conducting research studies on the corn borer. He was located at the Federal Laboratory because of the infestation was too light in Indiana for satisfactory investigations. Assistants have been provided for Mr. Ficht during the summer season. The United States Department of Agriculture has cooperated with our workers in a most gratifying way.

Infestation has now become heavy enough in certain places in northeastern Indiana to warrant the establishment of a field laboratory for our workers so they may more accurately study the insect under corn belt conditions.

Professor William Aitkenhead, chief of the Department of Agricultural Engineering, and R. H. Wileman have been carrying on studies in mechanical phases of corn borer control. New machinery has been designed to cut up the stalks and disk them into the soil. A study of the types of different kinds of farm implements, stalk cutters, corn harvesters, plows, stalk sweepers, etc., has been made for the purpose of adapting them more satisfactorily to the control of the corn borer.

L. E. Hoffman, Assistant County Agent Leader has been responsible for conducting a large amount of demonstrations and educational work having to do with the corn borer control.

The Agronomy Department, under the leadership of Professor A. T. Wiancko, has undertaken studies of the varieties of corn, methods and time of planting, the use of fertilizers, and methods of application to determine the best farm practice to reduce the injury from the corn borer. This work is being carried on in different parts of Indiana by S. R. Miles and O. B. Riggs.

CIRCULAR NO. 179 JANUARY, 1931

CODLING MOTH AND PEACH WORM INVESTIGATIONS

PROGRESS REPORT

The four stages in the life history of the codling moth are: Eggs, larvae, pupae, and adult moth. Note empty pupae skins, from which moths have emerged, protruding from two of the cocoons. Nearly natural size. (After U. S. Dept. Agriculture.)

PURDUE UNIVERSITY
AGRICULTURAL EXPERIMENT STATION
LAFAYETTE, INDIANA

The severe infestation of codling moths in the commercial orchards of the state has been the source of loss for some time. The Department of Entomology, under the leadership of Professor J. J. Davis, engaged G. E. Marshall to devote his time to codling moth and oriental fruit worm investigations. This work is being conducted in the vicinity of Bedford, Mitchell and Vincennes. A summer assistant is provided for Mr. Marshall who assists in the work during the busy season.

The Department of Horticulture, under the leadership of Professor Laurenz Greene, has played an important part in this work with the commercial orchardists. The demonstrations on the control of the codling moth were in charge of Professor C. L. Burkholder of that department. These demonstrations are linked closely with the investigations carried on by Mr. Marshall and practical results have been obtained for the fruit growers of the state.

Problems involving orchard sanitation, spray schedules, spraying materials, etc. were given first attention and immediate assistance was rendered to the growers which enabled them to better meet a bad situation and save many thousands of dollars.

The cooperation of the United States Department of Agriculture has been secured and the Bureau of Entomology has established a Federal station at Vincennes to carry on codling moth and oriental fruit worm and other studies. This work is in charge of Dr. F. H. Lathrop. The entire staff of the Vincennes station is cooperating in a fine way with the authorities of the Agricultural Experiment Station.

The codling moth will continue to be a menace to Indiana apple growers until more complete control measures, cheaper means of control and the elimination of excessive spray residue are accomplished. The continuation of the work on the oriental fruit worm is imperative. The results secured to date point the way for the development of this work.

The field laboratory at Bedford erected in the spring of 1927 for codling moth studies. Under such controlled conditions many studies bearing on the development of more efficient controls are being made.

PROGRESS REPORT ON CODLING MOTH INVESTIGATIONS

H. J. Reed, Assistant Director

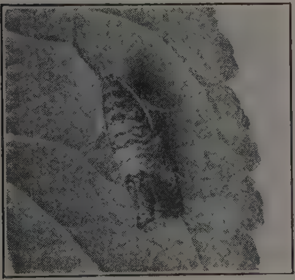
Purdue University
Agricultural Experiment Station

CODLING MOTH SITUATION

Indiana is assuming an important place in the fruit growing industry. Many sections of Indiana are favorably located and well adapted to the production of the highest quality apples and peaches. The average annual production of the orchards of Indiana is valued at approximately $6,000,000.00. One of the principal difficulties in the production of commercial apples has been the control of the codling moth. The damage caused by this insect has been increasing and threatens to cripple the apple industry in the state. The fruit growers of the state have made insistent demands for sufficient experimental and investigational work to develop effective controls.

The recent Federal regulations regarding the amount of arsenical spray residue on fruit for interstate shipment has made it imperative that control measures be developed which will not involve the usual amount of arsenate of lead in the spray schedule and which will not compel the grower to wash the fruit.

In the past three years, the oriental fruit worm has become established in Indiana. This insect will probably become the worst pest that the peach growers will have to control. The success of the peach growers depends upon their ability to produce a satisfactory crop of high quality. Indiana peaches have made a place for themselves on the principal peach consuming markets of the United States and have brought millions of dollars of new wealth into our state. Wormy fruit is a drug on the market and cause great losses to the state. If the thousands of acres of commercial orchards in this state are to continue to produce valuable crops, our growers must have control measures which will more satisfactorily protect their crops from insect damage. Much valuable work has been done during the past four years along two lines:



The adult codling moth is most active in the early evening hours. It is important to remember in timing first brood sprays that the moth is active and egg laying takes place only on nights when the temperature at sundown is above 60° F. (After U. S. Dept. Agriculture.)

(1). The making of careful studies of the insects, especially behavior studies bearing on the development of controls, life history, emergency periods, the application of new sprays, development of mechanical controls and an understanding of orchard practices as they affect the pests.

(2). The demonstration of the effectiveness of the best known methods of control. This includes orchard sanitation, packing house sanitation and spray schedules.

INVESTIGATOR GIVES FULL TIME TO PROBLEMS

A full time investigator was employed to carry on the entomological experiments outlined by Professor J. J. Davis, Chief of the Department of Entomology. A part-time assistant is employed for summer months to assist in the work. A field laboratory and insectory was provided on the Moses Fell Annex farm near Bedford for important detail studies in connection with this work. The problem of finding a spray material to replace lead arsenate is one of major importance. This is made necessary by the Federal regulations regarding spray residue on commercial fruit. Arsenate of lead has been effectively used in the standard codling moth spray solutions for a number of years. For the past four years, numerous spray materials have been tested with the hope of finding a satisfactory substitute. The most promising of these have been certain of the white oil sprays. Large scale investigations have been carried on in cooperation with growers at Orleans, Mitchell, and Bedford during the last two years. Much important work is yet to be done to determine methods of preventing spray injury to foliage and fruit before summer oil sprays can be unreservedly recommended. In cooperation with the State Chemist's Department, periodic residue analyses were made from samples of fruit representing each spray treatment to facilitate the recognition of the best spray program in respect to lead arsenate residue. Briefly, the results of the last two years were: They show a residue in excess of the federal tolerance on all fruits receiving the standard arsenate sprays but a residue below the tolerance on fruits receiving white oil sprays at the later part of the spraying season. The control obtained was approximately the same in each case.

Banding Experiments.—A great saving of time and money could be realized by growers if a tree band could be prepared which would kill all the codling moth larvae that had collected beneath it. Thousands of bands which have been given various chemical treatments have been tried out. A band which has given satisfactory results has been developed and a publication for growers is being printed. Further work is desirable to increase the efficiency of bands and decrease their cost. This work should provide a supplemental control, especially in badly infested orchards which will be of great value to the growers as has been shown in large scale tests.

Bait Experiments.—One of the fundamental principles underlying the development of baits is to find attractive material which will trap the codling moth in its flight. Through this work it has been found that certain aromatic chemicals, when added to the solutions in the bait pans, enhance the odor of the material and attract a portion of the moths. The work in 1929, demonstrates that bait traps placed in every other tree in the orchard was more efficient than bands placed on every tree. Bait pans are also proving a satisfactory method in determining the proper timing of sprays. Further study along this line is necessary, with special reference to reducing their cost to permit their use in practical control.

Sanitation.—Examinations made to determine all possible places that the codling moth may hibernate have shown that these insects will winter over in weed stems, corn stalks, apple twigs, matted grass, old bark, apple mummies, knot holes, cracks and in almost every conceivable place in the orchard. Around the packing house they may be found in the picking baskets, crates, crating and sizing machinery, cracks in the floor, walls, the ceiling and many other places. For this reason, recommendations have been made to growers to screen packing houses, to clean up brush and weeds and grass along fence rows, cut off dead limbs and scrape off and burn all excess bark on the trees. It has been found that the codling moth larvae which hibernate in the packing house in the fall continue to emerge until the first of August, the succeeding year. If these insects are not screened in, they will fly to the orchard and reproduce. Observations show conclusively that most serious infestations develop and are maintained, even in well sprayed orchards, because of improper conditions in packing houses, roadside stands, unsatisfactory orchard conditions and uncared for nearby orchards.

Life History and Behavior Studies.—It is imperative that some life history and behavior studies be carried on every year. Considerable data has been gathered through the laboratory tests which require special technique and partially controlled field experiments. This information is useful in making recommendations to the growers regarding the time for spraying.

Sanitation and Spraying.—Two phases of the codling moth work are being carried on by the Department of Horticulture.

(1). The clean-up and commercial spraying demonstrations

(2). A comparison of dust and liquid spray schedules for codling moth control.

Following the serious losses of 1926, every effort was made to cooperate with the commercial orchardists and secure a general clean-up in the orchards. This enabled the fruit growers to partially control the ravages of the insect the following year. During 1929 and 1930, another serious outbreak occurred and a very intensive campaign of spraying and banding was carried out.

Dust and Liquid Spraying. There has been considerable controversy regarding the relative merits of dusting and spraying for the control of the codling moth. For this work, a block of 175 twenty-year old trees of four leading commercial varieties is being used to compare the merits of these methods of protection. The results to date indicate that dust applications made up of arsenate of lead, in combination with sulphur and lime, are not as effective in the control of the codling moth as the same materials used in liquid form. In seasons of heavy and frequent rainfall, during the scab infection periods, dusts cannot be depended upon for even good commercial control.

PRESENT CODLING MOTH RECOMMENDATIONS BASED ON WORK OF PAST TWO YEARS

Packing House Sanitation.—1. Screening of packing sheds and holding all packages used in handling fruit inside a moth proof shed until after the first brood of moths emerges.

2. Care at roadside stands to prevent accumulation of fruit. Burn or bury all remnants and trash about stand.

Orchand Sanitation.—Elimination of conditions in the orchard which are favorable cocooning and hibernating places.

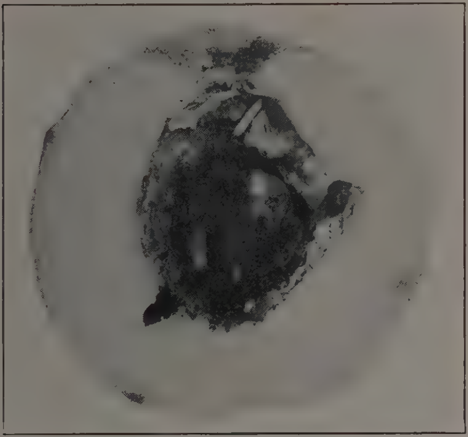
Spraying.—Thorough and heavy application for first brood worms. Continued spraying as recommended in emergency reports furnished by the Agricultural Experiment Station each season.

Banding.—The use of chemically treated bands in heavily infested orchards or where the insect is on the increase. This involves scraping of the trees to eliminate all cocooning places on the tree excepting the band applied. All scrapings should be burned.

Baits.—While promising results have been obtained from the use of bait traps, they cannot be recommended at this time because of the cost of maintaining them. A few bait traps will prove of value to the orchardist in enabling him to better time his spray applications.

ORIENTAL FRUIT WORM

Large scale spray experiments have been conducted on the Purdue-Vincennes orchard and a variety of materials used. Certain talc and hydrated lime sprays have somewhat reduced the infestation of oriental fruit worm in peaches. The spraying experiments for this year will include other materials which need to be tested out. Because of certain habits of the larva spraying with stomach poisons has proved ineffective.



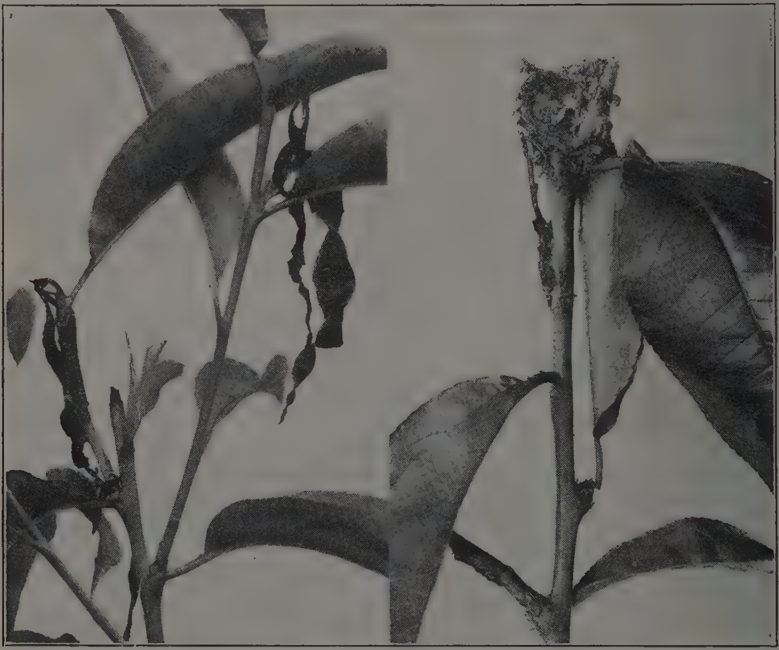
Injury to peach showing larva of oriental fruit worm and result of its feeding.

Hibernation Studies and Sanitation.—Detailed studies brought out the fact that 7 percent of the larvae of the oriental fruit worm hibernate below the snow line on the ground and 93 percent above. It has also been determined that 80 percent of all spring emergence during the last two years came from below the snow line out of weed stems from around the base of the tree and from mummied peaches on the ground. **For this reason, thorough sanitation and early spring cultivation are recommended.**

Parasites.—The experience of the investigators in New Jersey has emphasized the importance of introducing parasites to destroy the oriental fruit worm. The Department of Entomology has brought collections of these parasites to Indiana and has liberated one species (*Macrocentrus ancylivora*) in certain parts of the infested area. The first introductions were made in 1929 when more than 500 parasites were liberated near Vincennes and Mitchell. In 1930, recovery collections were made around the points of liberation, which assure us that these parasites are able to survive under Indiana conditions. In 1930, liberations were made at the Purdue-Vincennes farm near Vincennes, the Moses Fell Annex farm near Bedford and at Mitchell. Recovery collections were made at the end of the season indicate that the parasites were able to survive the extremely hot dry summer. Working in cooperation with the United States Department of Agriculture, Bureau of Entomology, liberations were made in nine other localities in the state ranging from the extremely southern end to the extremely northern part of the state. It is hoped that further liberations of this parasite which has shown a high degree of efficiency will be made this summer, and that other parasites can be introduced.

COOPERATION OF UNITED STATES DEPARTMENT OF AGRICULTURE

The Bureau of Entomology of the United States Department of Agriculture has recognized the serious situation caused by the insect and disease problems in the fruit industries and have rendered valuable cooperation in the establishment of the Federal station at Vincennes to cooperate on these problems. Much credit is due to this staff of government men. Among other things they are carrying on intensive laboratory studies with hundreds of possible insecticide materials, under the direction of Dr. F. H. Lathrop, and a large scale oriental fruit worm baiting experiment under the direction of W. P. Yetter, Jr.



Typical injury to peach twigs by the larvae of the oriental fruit worm. A, early summer injury; B, a type of injury, consisting of a mass of gum, leaves and frass, found in fall and winter.

Preparation and Use of Chemically Treated Bands for Codling Moth Control

By G. E. Marshall, *Department of Entomology*

Five years of laboratory and field experimentation with chemically treated bands have proven that such self-working bands can be used in place of ordinary bands in a commercial orchard at a very considerable saving of time and money to the fruit-grower. This is especially true in orchards where the trees have been and are to be banded every year with untreated bands and the larvae collected beneath the bands and killed by hand.

The number of larvae captured by self-working bands will vary as the infestation of the orchard concerned varies. In a badly infested orchard in 1930, the average number of larvae captured per band was, for "alpha," 105.5 (fig. 1), for "beta," 79.4, and for untreated, 81.5. On the contrary, in an orchard where the infestation was very light, the number of larvae captured per band was for "alpha," 19.3, for "beta," 15.6, and for untreated, 19.7. These two sets of figures gives the extremes. In three other orchards where experiments with these three kinds of bands were carried on, the number of larvae captured by each varied widely between these two extremes but in the same order.

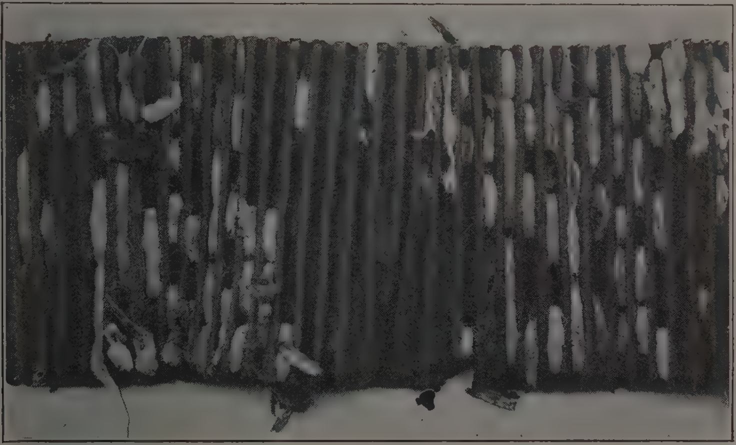

Fig. 1. Four inch chemically treated band showing cocoons of codling moth larvae. With rare exceptions every larva died before maturing.

Tests made in 1931 and 1932 showed that tallow could be used in place of oil in the "beta" bands with approximately as good results. Tallow is cheaper than oil, it prevents oils from soaking into the band and the temperature of the material need not be as high when the bands are dipped. Bands dipped in tallow and beta naphthol have a coating which will not crack off if handled in cool weather.

Aside from eliminating the worry of frequently examining bands during the summer the chemically treated or self-working bands avoid a large part of the expense of banding. For example, in one southern Indiana orchard there are 6,021 trees, all of which are regularly banded. In 1930 the bands were untreated and necessitated examination every ten days during the season. They were run nine times and, including the initial application, handled ten times. One man can visit not more than 200 bands a day. At $1.25 a day, it cost $47.50 for each run of the bands, or a total of $475.00. On the other hand, the cost of applying and removing the self-working bands was $90.00, plus the cost of treating, which would amount to not over $180.00, a total of $270.00. This amounts to a saving of at least $205.00.

Four factors of importance have been considered in the development of self-working bands as a supplementary measure in the control of the codling moth. These include,—chemical treatment, width, texture and height on the tree.

Banding Material. The bands should be made of one-faced corrugated cardboard, four inches wide, with four or five corrugations per inch.

Chemical Treatment. Three kinds of chemical treatments have given results warranting recommendation. These are alpha-naphthol-oil-parawax, beta-naphthol-oil and beta-naphthol-tallow.

Alpha-naphthol-Oil-Parawax Bands

The following materials (fig. 2) were needed for the preparation of the alpha-naphthol-oil-parawax bands:

e. Alpha-naphthylamine (technical grade), 1¾ pounds.
b. Paraffin base oil, of 200 to 300 viscosity, 1 pint.
c. Parawax, ⅜ pound.

The above amounts are sufficient to treat 50 bands.

Preparation of Bands. Select a breezy day and treat bands out-of-doors. Handle the bands with gloves and do not breathe the fumes of the chemicals. Put materials together in a large bucket or a small tub over a hot fire. When all the alpha-naphtholamine has melted and small yellow bubbles begin to form on the surface, dipping of bands may be started. Rolls of the corrugated paper of convenient size for dipping may be handled by strings tied to each side of the rolls. These are dipped flat side first into the hot chemicals. (Fig. 3.) If the mixture is hot enough, the rolls need only be half submerged and the liquid will foam up through the corrugations of the paper and spread out on top of the roll. As soon as this foam has spread over the entire surface,

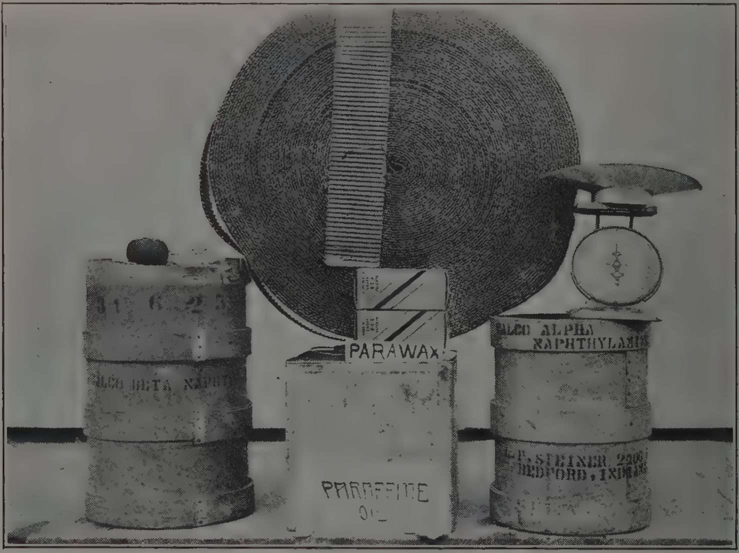

Fig. 2. Materials needed in the preparation of either alpha- or beta-naphthol bands.

raise the roll and let it drain back into the bucket. After draining, lay it aside where it can be turned over every minute or two for 10 or 12 minutes to prevent the material from running out of the bands and thus retain as much of the chemical as possible. Bands so treated will appear very oily for some time after treatment and should be a dark purplish-brown color. These bands have a very unpleasant odor.

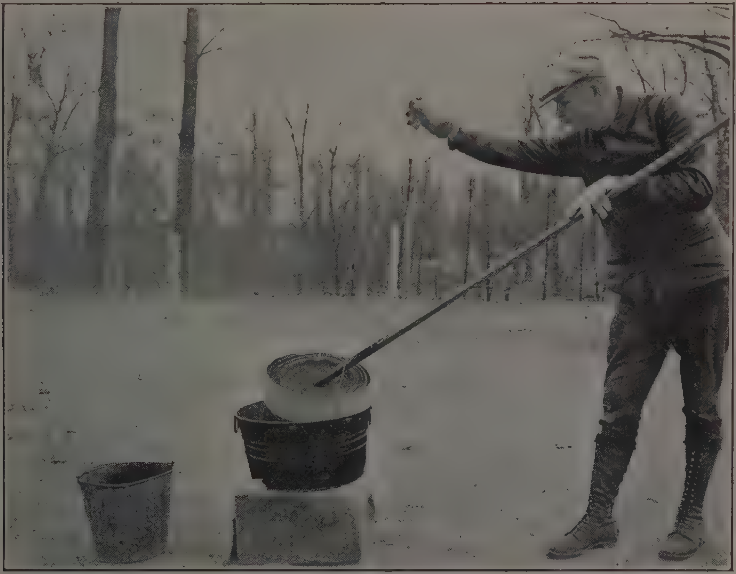

Fig. 3. Process of treating a roll of corrugated cardboard in the preparation of chemically treated bands.

Beta-naphthol Bands

The beta-naphthol-oil bands may be made in exactly the same way and using the same amounts of each material with these few exceptions: (a) no parawax is used; (b) beta-naphthol is used in place of the alpha-naphtholamine. It goes into solution at a much higher temperature and hardens much more rapidly. Beta-naphthol-oil bands are a yellow-brown color, rendered grey by crystals of naphthol which form on the surface of the paper. The oil is not conspicuous.

Beta-naphthol-tallow bands are made by using the same amounts of materials as for beta-naphthol oil bands but tallow is used in place of oil.

Precautions. A steady fire is best in the preparation of either type of band. If the liquid it too hot not enough of the chemical will be deposited in the bands at one treatment. The temperature at which the chemical will slowly foam up through the paper is best. The flash point of this mixture is 410° F., and if it is exposed directly to the flames at lower temperatures, it may catch fire. The fumes from alpha- and beta-naphthol are dangerous. Also, these materials are caustic to the skin and gloves should be worn while handling treated bands.

Use of Chemical Bands

The efficiency of any kind of tree band is directly dependent on the removal of every bit of excess bark on the tree trunk and larger branches.

Chemical bands darken the bark where applied. The beta-naphthol-tallow bands leaving the least discoloration. The discoloration left by the alpha-naphtholamine bands is much more noticeable than is that left by the beta-naphthol bands. These chemical bands have been applied to the same trees and in the same identical positions for five consecutive years with no noticeable injury. Solid bands of burlap, etc., with chemical treatments have produced injury. The corrugated cardboard must be used for all chemically treated bands.

Each year the highest single band catch has been with an "alpha" band, but since the odor of the bands is so unpleasant and the difference in catch so small most growers prefer the "beta" bands.

Bands should be applied before June 15 and should be placed about 18 to 24 inches above the ground with the corrugations next to the tree. Every care must be used to see that they fit snugly around the tree trunk. In case the tree to which the band is applied has a nitch in one side, a big headed tack should be used to hold the band against the bark in the groove. Often three to five tacks may be needed to make the band perfect fitting. The ends of the paper may be held in place by one tack and should overlap at least an inch and a half. A magnet hammer may be an aid in handling tacks with gloved hands. Bands should be removed and burned not later than April 15 the following year.

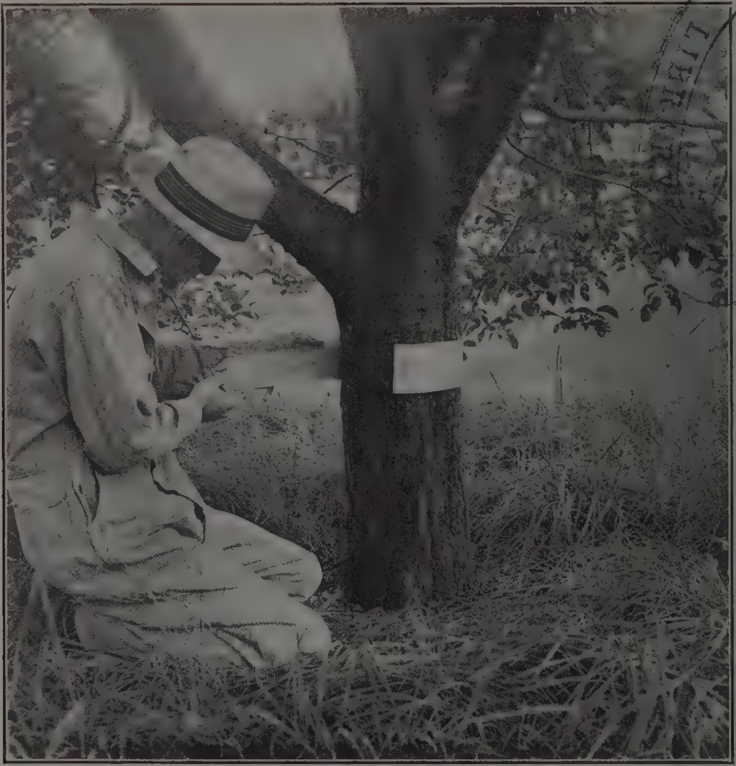

Fig. 4. Care should be taken in applying the band to see that it fits snugly about the tree and also the loose bark should be thoroughly removed from the tree before the band is applied.

Cost of Materials. The prices paid for materials used in the preparation of bands in 1932 were as follows:

Alpha-naphthylamine in 25 lb. lots	38c per lb.
Beta-naphthol in 25 lb. lots	27c per lb.
Oil in 10 gal. lots	18½c per gal.
Corrugated paper (4-inch strips 125 feet long)	12¾c
Tallow in 100 lb. lots	2c per lb.

Oil may be obtained from any filling station or oil company. Parawax is sold by most grocers and druggists.

ARIZ. UNIV. LIB. JUN 15 1931

Circular No. 181 April, 1931

COMMERCIAL FEEDING STUFFS

Rats of same age. Small rat received protein deficient ration while large rat received ration adequate in protein.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular contains a condensed report of Indiana's 1930 commercial feed inspection.

It is estimated that 512,096 tons of commercial feeds with a retail value of $24,293,652 were sold in Indiana during the year 1930. The inspectors of the State Chemist department secured 2,840 samples, or approximately one sample for each 180 tons of commercial feeds sold in this state.

All of the 2,840 samples collected were examined microscopically and 2,441 were analyzed chemically. It was found that 80 per cent of the samples were equal to or better than the manufacturer's guarantee as declared on the official tag. Of the 551 samples incorrectly guaranteed, 335 of them would be classed as seriously deficient or misbranded and sold in violation of the law. Shipments not tagged or seriously deficient were withdrawn from sale and manufacturers relabeled such feeds correctly and made refunds amounting to $1,979 to the agents and consumers.

Explanation of terms used in the analysis of feeds.

Table I Average analyses of the common cereals and by-product feeds.

Table II Estimated Sales of various classes of feeding stuffs.

Table III Withdrawals from sale.

Table IV Summary of the annual tonnage and expenditures for commercial feeding stuffs since 1911.

Definitions of feeding stuffs.

Table V Summary of inspection giving the standing of each feed manufacturer.

COMMERCIAL FEEDING STUFFS

H. R. KRAYBILL, State Chemist

O. S. ROBERTS, P. B. CURTIS, C. C. YUND, G. E. HALLIDAY, D. M. DOTY

The Indiana Feeding Stuffs law is primarily a correct labeling law. It requires the feeding stuff to be correctly labeled with official Indiana State labels or tags in order that the prospective buyer may have the information necessary to determine whether the feed is the kind which he wishes to buy. The official tag which bears the facsimile signature of the State Chemist gives the manufacturer's minimum guarantees for crude protein and crude fat and a maximum guarantee for crude fiber. Furthermore the tag states the specific name of each ingredient used in preparing the feeding stuff. Mineral feeds containing no organic ingredient do not require the usual chemical feed guarantee but do require a declaration of each ingredient contained therein and the minimum percentages of calcium (CaO), phosphorus (P_2O_5), iodine (I) and the maximum percentage of salt ($NaCl$) if same are present. With this information the purchaser is able to distinguish between superior and inferior feeds and to make an intelligent and economical purchase.

During the year 1930 the State Chemist collected 2,840 samples of commercial feeding stuffs from manufacturers, agents and farmers in the various sections of the state. One inspection sample was secured from approximately each 180 tons of commercial feed sold in Indiana. All of the 2,840 samples collected were examined microscopically and 2,441 of them were analyzed chemically for moisture, crude protein, crude fat, crude fiber and ash content. Those not analyzed were largely from shipments previously analyzed or were mineral feeds which required a different chemical analysis. Many of the samples drawn represented carload shipments.

Of the 2,840 samples secured 551 of them were found to be guaranteed incorrectly and 335 were classed as being seriously deficient or misbranded and not sold in accordance with the Indiana Feeding Stuffs law. The year's inspection showed that 80 per cent of the samples were equal to or better than the manufacturer's guarantee, as compared to 82 per cent in 1929.

Estimated Sales of Commercial Feeding Stuffs in 1930

Calculating the annual tonnage of commercial feeding stuffs sold from the number of tags issued by the State Chemist, it is estimated that 512,096 tons of commercial feeding stuffs with a retail value of $24,293,652 were sold in Indiana in 1930. Compared with the sales of 1929 this represents an increase of 13,209 tons but a decrease of $2,198,125 in expenditures. This decrease in expenditures was apparently due to the rapid decline in feed prices during the latter half of the year. From Table II the principal decreases in tonnage sold were for hominy feed, linseed oil meal, mineral feeds and condimental feeds while the principal increases were for cottonseed meal, poultry scratch feed and poultry mash.

Refunds and Withdrawals from Sale

During the year 1930 the sum of $1,979 was refunded by 74 feed manufacturers on 133 shipments of deficient feed. The payment of refunds does not nullify the right of anyone in the state to call cases of deficiency to the attention of the prosecuting attorney. On the other hand by making these refunds the manufacturer indicates his good intentions and does all that he can to correct the violation of the law.

Non-tagging still remains the most frequent cause for withdrawal of commercial feeding stuffs from the open market. Of the 733.0 tons withdrawn from sale in 1930 by the State Chemist, 466.6 tons, representing 146 shipments, were removed from sale on account of non-tagging. Thirty-one protein deficient shipments representing 105.3 tons were withdrawn from sale while 19 shipments comprising 91.8 tons were removed on account of misbranding. In practically all of the above cases the manufacturers furnished proper tags for the non-tagged feed and either replaced the deficient shipments with feed up to guarantee or retagged the feed with a correct guarantee.

Attention!

The official tag required by the Indiana feed law bears the facsimile signature of the State Chemist and contains the maunfacturer's guarantee.

Dealers and consumers should not accept any shipments without State Chemist tags or with such tags showing alterations. When such shipments are received they should not be accepted until official Indiana tags are furnished. When these are received one should be attached to each bag of 100 pounds or fraction thereof before offering or exposing for sale or selling the feed.

Manufacturers should not neglect to attach proper tags to each and every bag of feed shipped into Indiana in order to protect their dealers.

Distributors shipping feed into Indiana should request the manufacturer to furnish Indiana tags for such shipments before distributing same to Indiana dealers or consumers.

Dealers should be careful in handling the feed when unloading not to tear the tags off the sacks.

Carelessness on the part of the manufacturer, distributor or dealer may lead to serious violations of the Indiana Feeding Stuffs law.

Registration of all feeds are permanent. However, when changes are made in the chemical guarantee or ingredients in a brand of feed it is necessary to reregister such feed with the State Chemist. In registering commercial mixed feeds, trade names are not permitted in the statement of the ingredients. Furthermore, the source of such ingredients as calcium carbonate and calcium phosphate is required on the certificate of registration. When screenings are used in a mixture, the source of same must be stated. Indefinite names such as "grain screenings" will not be accepted. Also screenings must not contain any seed or other product injurious to animals and, except in poultry feeds, must be ground fine enough in all cases to destroy the viability of the seeds contained therein.

Dealers and consumers are requested not to send miscellaneous samples of feed to the State Chemist without giving full information as to name of manufacturer, brand name, amount on hand and reasons for desiring an analysis. This also includes samples of feed suspected of having caused ill effects on animals or poultry. If sufficient quantity of such feed is on hand perhaps an official sample can be drawn under the direction of the State Chemist.

The State Chemist Department does not make recommendations regarding feed formulas. If such information is desired the various Departments of the Purdue University Agricultural Experiment Station such as the Animal, Dairy, and Poultry Husbandry Departments will give to you their feeding results upon request.

Manufacturers having difficulty in computing proper guarantees for their adopted feed formulas are invited to write to the State Chemist Department regarding this matter. Table I containing the Average Analyses of Cereals and By-Products will be of great assistance to those who wish to calculate safe guarantees for their feeds.

Agents and farmers should familiarize themselves with the Explanation of Terms Used in the Analysis of Feeding Stuffs as well as with the Definitions of Feeding Stuffs. Table V "The Summary of Feed Inspection" is worth consideration by those who purchase commercial feeds.

Animal By-Products

The animal by-products most frequently used for feeding purposes include tankage, meat scraps, meat and bone scraps, dried blood and bone meal. These products are valuable as protein and mineral supplements to farm grains. When purchasing tankages or meat scraps the comparative cost per unit of protein should always be considered.

Alfalfa Products

During the past year substitution of alfalfa meal for alfalfa leaf meal was found in several poultry mashes and a few hog feeds. Manufacturers should bear in mind that when changes are made in the ingredients it is necessary to reregister the feed containing them.

Condimental Poultry and Stock Feeds

Although not all condimental feeds come under the Indiana Feeding Stuffs law it is gratifying indeed to note the decrease in tonnage and expenditures for this class of feed as recorded in Table II. This continual decrease in tonnage sold seems to indicate that the feeder is looking upon this class of feed with scrutiny.

Cottonseed Meals

Compared with the year 1929, a greater number of cottonseed meal samples were found to be seriously deficient in crude protein. Furthermore, there was a tendency for the samples to exceed their crude fiber guarantee which resulted in the necessity of re-registering several brands of cottonseed meal.

Dried Buttermilks

A tentative minimum standard of 5.5 per cent fat for dried buttermilk sold in this state was set effective January 1, 1931.

The purpose of this fat standard is to aid the correct labeling of dried skimmed milk and dried buttermilk. There is no desire to discourage increased efficiency in the churning process but after thorough investigation not only in Indiana but in several other states it was concluded that a pure dried buttermilk will practically always contain at least 5.5% fat. The method employed in determining the fat content is the official Roese-Gottlieb method.

Mill By-Products

This class of feed includes such wheat products as wheat bran, wheat middlings, flour middlings, wheat red dog, wheat low grade feed flour and wheat mixed feed. Each of these products is defined under "Definitions of Feeding Stuffs." If any of these wheat products is derived from durum wheat it must be stated on the tag.

Poultry Mashes

During the year 1930 the estimated tonnage of poultry mash sold in this state was 142,406 tons with a retail value of $7,903,533. Sales for this class of feed have steadily increased for a number of years, particularly during the last six years when the all mash system of feeding has been stressed. Manufacturers incorporating cod liver oil in their mashes should bear in mind that such mashes require separate registrations from those of plain mashes. The official Indiana State tag must state cod liver oil as an ingredient if same is added.

Proprietary Feeds

As indicated in Table II this class of feed has been divided into various sub-classes, namely, cattle and dairy feeds, hog and pig meals, horse and mule feeds, calf meals, and rabbit and dog feeds. These ready mixed feeds constitute a very important class of commercial mixed feeds. Probably there is no other class of feed where there exists such a wide range in nutritive value. Many of these feeds are of the finest quality while others contain ingredients of very little feeding value.

Explanation of Terms used in the Analysis of Feeding Stuffs

Moisture is the varying quantity of water occurring in feeding stuffs which can be driven off by heat at the temperature of boiling water. The amount of water present varies with the temperature, moisture content of the air, process of manufacture and the character of the substance. In most concentrates this value ranges from five to fifteen per cent.

Crude Fat consists mainly of fats and oils with small amounts of waxes, resins, coloring matter and similar substances, dissolved from feeding stuffs by dry ether. In calculating the heat and energy value of a feed, the fat is considered 2.25 times greater than that of either carbohydrates or protein.

Crude Protein is the term applied to the nitrogenous constitutes of a feeding stuff. It is obtained by multiplying the total nitrogen by 6.25. Protein is the most important as well as the most costly constituent in a feed. Plants have the power of building up protein from the inorganic elements of the soil and air while animals must secure their protein from the plants or other animals. The plant proteins contain varying amounts of the essential amino acids, therefore it is necessary to carefully select a variety of feeds which will furnish the essential amino acids economically.

Crude Fiber is the woody portion of a feeding stuff, for the most part cellulose, and is insoluble in dilute acids and alkalis. Most of the common seeds and grains contain very little fiber while the hulls, husks and stems are high in this constituent. In poultry and swine, crude fiber when present in considerable quantities exerts a retarding influence on the digestion of nutrients present.

Ash, the mineral matter of plants, is the residue left after burning a feeding stuff at low redness. It consists chiefly of the phosphates, sulphates, chlorides and carbonates of sodium, potassium, calcium and magnesium. The calcium and phosphorous are absolutely essential for the proper nutrition of the animal.

Nitrogen Free Extract consists of sugars, starches, pentoses, non-nitrogenous organic acids, etc., and is determined by subtracting the sum of moisture, crude fat, crude protein, crude fiber and ash from 100.

Carbohydrates is the sum of the crude fiber and Nitrogen-free extract.

TABLE I—Average Analysis of Cereals and By-Products

Material	Description of	Pounds in one hundred		
		Crude fat	Crude protein	Crude fiber
Alfalfa meal	Entire ground hay	1.5	13.0	33.0
Alfalfa leaf meal	Largely alfalfa leaves	2.5	20.0	18.0
Barley	Whole or ground	1.8	11.0	6.0
Beet pulp	Dried	0.9	8.5	18.0
Blood (dried)	Blood meal	0.5	80.0	none
Bone (raw)	Raw bone	3.0	20.0	1.0
Bone (steamed)	Steamed bone	0.5	6.0	1.0
Brewers' dried grains	From manufacture of beer	6.0	26.0	15.0
Buckwheat	Whole or ground	2.2	10.0	10.0
Buckwheat mixed feed	Entire product from manufacture of buckwheat flour	3.2	12.0	28.0
Buckwheat middlings	Entire product from manufacture of buckwheat flour, except the hulls	7.3	28.8	6.4
Buttermilk (dried)	Dried buttermilk	5.5	30.0	none
Buttermilk (condensed)	Condensed buttermilk	2.0	10.0	none
Cane seed	(Sorghum) removed from head and cleaned	2.5	9.0	2.5
Charcoal	Charcoal	none	none	90.0
Cob meal	Ground corn cob	0.5	2.0	31.0
Cocoanut oil meal	Dried cocoanut meats with partial extraction of oil	8.0	22.0	9.0
Corn	Old corn No. 2	4.0	9.5	2.0
Corn and cob meal	Ear corn (old)	3.5	8.0	8.0
Corn bran	Containing little corn germ	2.5	7.0	10.0
Corn mill feed	Corn bran, germ and some meal from manufacture of meal or corn flour	7.4	11.0	4.2
Corn feed meal	Manufacture of cracked corn	3.5	9.0	2.0
Corn germ oil meal	Corn germ with part of the oil removed	8.0	20.0	8.0
Corn gluten feed	Remains after the larger part of starch and germ is removed	2.0	25.0	7.0
Corn gluten meal	From manufacture of corn starch and glucose	1.0	42.0	2.0
Corn screenings	Small and broken grains of corn, small pieces cob, etc., removed from shelled corn	2.7	8.6	8.6

TABLE I—Continued.

Material	Description of	Pounds in one hundred		
		Crude fat	Crude protein	Crude fiber
Cottonseed meal (prime quality)	Sold as 36 per cent protein	6.0	36.0	14.0
Cottonseed meal (prime quality)	Sold as 41 per cent protein	6.0	41.0	12.0
Cottonseed meal (prime quality)	Sold as 43 per cent protein	6.0	43.0	10.0
Cottonseed feed	Below 36 per cent protein	4.0	22.8	22.0
Cottonseed hulls	Contains trace of lint and meal adhering	1.8	4.6	38.0
Cowpea	Seeds, pods removed	1.4	20.8	4.1
Distillers' grain (dried)	From corn or rye	9.0	27.0	12.0
Emmer	Often called spelt	2.0	11.5	10.0
Fish meal	Dried ground tissues of fish with or without the extraction of part of the oil	6.0	55.0	2.0
Flaxseed	Whole grain or meal without extraction of oil	32.0	22.0	7.0
Flax plant by-product	Shives, pods, etc.	2.1	15.0	31.0
Flaxseed screenings	Small and broken grains, flaxseed, weed seed and other foreign material cleaned from flaxseed	8.0	14.0	14.0
Hominy feed, meal or chop	Manufacture of hominy grits or meal by degerminator process	6.0	11.0	6.0
Kafir corn	Milo	2.5	10.0	2.5
Kelp (dried)	Ground dried kelp	1.0	6.0	10.0
Linseed meal (old process)	Oil extracted by pressure	6.0	34.0	8.0
Malt sprouts	Sprout of the barley grain	1.3	27.9	12.1
Meat scraps	Ground dry rendered residue from animal tissues	6.0	50.0	3.0
Millet	Italian millet seed	3.9	10.3	9.4
Milo	Whole or ground	2.5	10.7	2.5
Molasses	From beets	none	3.0	....
Molasses	Blackstrap from cane	none	3.0	....
Oats	Ground or whole	4.0	11.0	11.0
Oat-clipped by-product	Clippings	2.0	9.0	30.0
Oat-groats	Kernels of oat berry	6.5	15.0	2.0
Oat hulls	Oat hulls	1.5	4.0	32.0
Oat meal mill by-product	Oat hulls and oat shorts	1.5	6.0	28.0
Oat middlings	Floury portion of oat groat	5.0	15.0	5.0

Peanut oil feed	Peanut meats and peanut hulls	6.0	30.0	25.0
Peanut oil meal	Residue after the extraction of part of the oil from peanut kernels	6.0	40.0	6.0
Peanut shells	Whole or finely ground	1.2	5.5	70.9
Rice bran	Cuticle layer beneath hull	12.0	12.0	12.0
Rye	Rye	1.5	11.0	2.0
Rye feed	Rye feed	3.5	16.0	5.0
Skimmed milk (dried)	Dried skimmed milk	0.5	30.0	none
Soybean	Seed pods removed	19.0	35.0	5.0
Soybean oil meal	Ground	6.0	40.0	6.0
Sunflower seed	Whole or ground	19.0	16.0	30.0
Tankage (digester)	60 per cent reinforced with concentrated tank water or dried blood	6.0	60.0	3.0
Unscreened flaxseed oil feed	Flaxseed meal and flaxseed screenings	6.0	30.0	9.0
Velvet bean feed	Velvet beans and pods	4.0	19.0	17.0
Wheat	Whole or ground	1.9	11.9	2.4
Wheat bran (soft)	Wheat bran	3.5	14.5	8.0
Wheat bran (hard)	Wheat bran	4.0	16.0	10.0
Wheat middlings	Wheat middlings	3.5	15.5	6.0
Wheat standard middlings	With and without screenings	4.0	16.0	9.5
Wheat red dog flour	Red dog flour	3.5	15.0	4.0
Wheat mixed feed and mill run screenings	Bran, middlings, red dog flour and screenings	3.5	15.0	8.0
Whey (dried)	Dried whey	0.5	12.0	none

DEFINITIONS OF FEEDING STUFFS

Meal is the clean sound ground product of the entire grain, cereal, or seed which it purports to represent.

Chop is a ground or chopped feed composed of one or more different cereals or by-products thereof. If it bears a name descriptive of the kind of cereals, it must be made exclusively of the entire grains of those cereals.

Ear Corn Chops is corn and cob chopped, without the husk, with not a greater proportion of cob than occurs in the ear corn in its natural state.

Head Chops consists of the entire head of the grain sorghums chopped, and should bear the name of the sorghum from which it is made. This includes, among others, kaffir head chops, milo head chops, feterita head chops, and sorghum head chops.

Head Stems consists of the head of the grain sorghums, from which the grain has been removed, and should bear the name of the sorghum from which it is made.

Alfalfa Products

Chopped Alfalfa is the entire alfalfa hay, chopped and not ground finely enough to become a meal. It must not contain an admixture of alfalfa straw or other foreign material.

Alfalfa Meal is the product obtained from the grinding of the entire alfalfa hay, without the addition of any alfalfa stems, alfalfa straw or foreign material, or the abstraction of leaves. It must be reasonably free from other crop plants and weeds, and must not contain more than 33 per cent of crude fibre.

Alfalfa Leaf Meal is the ground product consisting chiefly of leafy materials separated from alfalfa hay. It must be reasonably free from other crop plants and weeds and must not contain more than 18 per cent of crude fibre.

Alfalfa Stem Meal is the ground product remaining after the separation of the leafy material from alfalfa hay or meal. It must be reasonably free from other crop plants and weeds.

Animal By-Products

Blood Meal is ground, dried blood.

Blood Flour is dried blood, prepared by special processes and reduced to a fine powder.

Digester Tankage, Meat Meal Tankage or Feeding Tankage is the residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry-rendering or a mixture of the products made suitable by drying and grinding. When these products contain more than 10 per cent phosphorus (P_2O_5) they shall be designated Digester Tankage with Bone, Meat and Bone Meal Digester Tankage, Meat and Bone Meal Tankage, or Feeding Tankage with Bone. If they bear a name descriptive of their kind, composition or origin they must correspond thereto.

Meat Scraps is the ground dry rendered residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice. When this product contains more than 10 per cent phosphorus (P_2O_5), it shall be designated Meat and Bone Scrap. If they bear a name descriptive of their kind, composition or origin they must correspond thereto.

Raw Bone Meal is the dried, ground product suitable for animal feeding, obtained by cooking in water at atmospheric pressure, undecomposed bone, just enough to remove excess fat and meat. It must not contain less than 23 per cent of protein.

Steamed Bone Meal is the dried, ground product suitable for animal feeding obtained by cooking bones with steam under pressure.

Special Steamed Bone Meal is the dried, ground product suitable for animal feeding obtained by cooking dried bone after the removal of grease and meat fibre with steam under pressure in the process of obtaining gelatine or glue.

Apple Products

Dried Apple Pomace is the sound, dried residue obtained by the removal of cider from apples.

Dried Apple Pectin Pulp is the sound, dried residue obtained by the removal of pectin from apple products.

Barley Products

Barley Hulls are the outer coverings of the barley.

Barley Feed is the entire by-product resulting from the manufacture of pearl barley from clean barley.

Barley Mixed Feed is the entire offal from the milling of barley flour from clean barley and is composed of barley hulls and barley middlings.

Ground Barley is the entire product obtained by grinding clean sound barley, containing not less than 90 per cent pure barley and not more than 10 per cent of other grains, weed seeds and other foreign material and not more than 6 per cent fiber; provided that no portion of this stated 10 per cent of other grains, weed seeds or other foreign material shall be deliberately added.

Mixed Feed Barley is the entire product obtained by grinding country run barley containing not less than 75 per cent pure barley and not more than 25 per cent of other grains, weed seeds and other foreign material; provided that no portion of this stated 25 per cent of other grains, weed seeds or foreign material shall be deliberately added. The ingredients must be stated as barley, other grains, weed seeds and foreign material.

Brewers' and Distillers' Products

Brewers' Dried Grains are the properly dried residue from cereals obtained in the manufacture of beer.

Distillers' Dried Grains are the dried residue from cereals obtained in the manufacture of alcohol and distilled liquors. The product shall bear the designation indicating the cereal predominating.

Distillers' Corn Solubles, a by-product from the manufacture of alcohol from corn, is a mash liquor concentrated after the removal of the alcohol and wet grains.

Distillers' Rye Solubles, a by-product from the manufacture of alcohol from rye, is a mash liquor concentrated after the removal of the alcohol and wet grains.

Distillers' Corn and Rye Solubles, a by-product from the manufacture of alcohol from corn and rye, is a mash liquor concentrated after the removal of the alcohol and wet grains.

Malt Sprouts are the sprouts of the barley grain obtained in the malting process. Sprouts derived from any other malted cereal must be designated by the name of that cereal.

Yeast or Vinegar Dried Grains are the properly dried residue from the mixture of cereals, malt and malt sprouts (sometimes cottonseed meal) obtained in the manufacture of yeast or vinegar, and consists of corn or corn and rye from which most of the starch has been extracted, together with malt added during the manufacturing process to change the starch to sugars, and malt sprouts (sometimes cottonseed meal) added during the manufacturing process to aid in filtering the residue from the wort and serve as a source of food supply for the yeast.

Buckwheat Products

Buckwheat Shorts or Buckwheat Middlings are that portion of the buckwheat grain immediately inside the hull after separation from the flour.

Corn Products

Corn Bran is the outer coating of the corn kernel.

Corn Feed Meal is the by-product obtained in the manufacture of cracked corn, with or without aspiration products added to the siftings. This name is also correctly applied to the by-product obtained in the manufacture of table meal from the whole grain by the non-degerming process.

Grits are the hard, flinty portions of Indian corn containing no bran or germ.

Corn Gluten Meal is that part of commercial shelled corn that remains after the separation of the larger part of the starch, the germ and the bran by the processes employed in the manufacture of cornstarch and glucose. It may or may not contain corn solubles.

Corn Gluten Feed is that portion of commercial shelled corn that remains after the separation of the larger part of the starch and the germs by the processes employed in the manufacture of cornstarch and glucose. It may or may not contain corn solubles.

Maltose Process Corn Gluten Feed is the dried residue from degermed corn, after removal of starch in the manufacture of malt syrup.

Hominy Feed, Hominy Meal or Hominy Chop is the kiln-dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the white corn kernel obtained in the manufacture of hominy, hominy grits, and cornmeal by the degerming process.

Yellow Hominy Feed, Yellow Hominy Meal or Yellow Hominy Chop is a kiln-dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the yellow corn kernel obtained in the manufacture of yellow hominy grits and yellow cornmeal by the degerming process.

Corn Oil Cake consists of the corn germ from which part of the oil has been pressed and is the product obtained in the wet milling process of manufacture of corn starch, corn syrup, and other corn products.

Corn Oil Meal is ground corn oil cake.

Corn Germ Cake consists of corn germ with other parts of the corn kernel from which part of the oil has been pressed, and is the product obtained in the dry milling process of manufacture of cornmeal, corn grits, hominy feed, and other corn products.

Corn Germ Meal is ground corn germ cake.

Cottonseed Products

Cottonseed Meal is a product of the cottonseed only, composed principally of the kernel with such portion of the hull as is necessary in the manufacture of oil; provided that nothing shall be recognized as cottonseed meal that does not conform to the foregoing definition and that does not contain at least 36 per cent of protein. Cottonseed meal shall be graded and classed as follows:

1. **Cottonseed Meal,** Prime Quality. Cottonseed meal, prime quality, must be finely ground, not necessarily bolted, of sweet odor, reasonably bright in color, yellowish, not brown or reddish, free from excessive lint, and shall contain not less than 36 per cent of protein. It shall be designated and sold according to its protein content. Cottonseed meal with 36 per cent of protein shall be termed "36 per cent Protein Cottonseed Meal, Prime Quality," and higher grades similarly designated (as "43 per cent Protein Cottonseed Meal, Prime Quality"), etc.

2. **Cottonseed Meal, Off Quality.** Cottonseed meal not fulfilling the above requirements as to color, odor and texture shall be graded "36 per cent Protein Cottonseed Meal, Off Quality," and higher grades similarly designated.

Cottonseed Feed is a mixture of cottonseed meal and cottonseed hulls, containing less than 36 per cent of protein.

Cold, Pressed Cottonseed is the product obtained from the subjection of the whole undecorticated cottonseed to the cold pressure process for the extraction of oil and includes the entire cottonseed less the oil extracted.

Ground Cold Pressed Cottonseed is the product obtained by grinding cold pressed cottonseed.

Linseed and Flax Products

Linseed Cake or Meal is oil cake or meal made from flaxseed; provided that the final product shall contain less than 6 per cent of weed seeds and other foreign materials and; provided further, that no portion of the stated 6 per cent of weed seeds and other foreign materials shall be deliberately added.

Old Process Oil Meal, Old Process Linseed Meal is oil meal as defined or linseed meal as defined produced by crushing, cooking and hydraulic pressure.

New Process Oil Meal, New Process Linseed Meal is oil meal as defined or linseed meal as defined produced by crushing, heating and the use of solvents.

Flax Plant By-product is that portion of the flax plant remaining after the separation of the seed, the bast fiber and a portion of the shives, and consists of flax shives, flax pods, broken and immature flax seeds, and the cortical tissues of the stem.

Ground Flaxseed or Flaxseed Meal is the product obtained by grinding flaxseed which has been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process; provided that the final product shall contain less than 4 per cent of weed seeds and other foreign materials, and; provided further, that no portion of the stated 4 per cent of weed seeds and other foreign materials shall be deliberately added.

Unscreened Flaxseed Oil Feed Cake is the product obtained by extraction of part of the oil from unscreened flaxseed by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents. The ingredients shall be stated as partially extracted flaxseed and foreign seeds (wheat, wild buckwheat, pigeon grass, wild mustard, etc.).

Ground Unscreened Flaxseed Oil Feed is the ground unscreened flaxseed oil feed cake.

Screenings Oil Feed is the ground product obtained after extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents from the smaller imperfect grains, weed seeds and other foreign materials, having feeding value, separated in cleaning the grain. The name of the grain from which the screenings are separated shall be prefixed to "screenings oil feed."

Oil Cake is the product obtained after the extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents, from seeds which have been screened and cleaned of weed seeds, and other foreign materials by the most improved commercial process. When used alone the term "Oil Cake" shall be understood to designate linseed cake as defined. When used to cover any other products the name of the seed from which it is obtained shall be prefixed to the words "Oil Cake."

Oil Meal or Ground Oil Cake is oil cake ground to a meal.

Marine Products

Fish Meal is clean dried ground tissues of undecomposed whole fish and/or fish cuttings with or without the extraction of part of the oil.

Fish Residue Meal is the clean, undecomposed residue from the manufacture of glue from non-oily fish.

Crab Meal is prepared from the undecomposed waste of the crab industry and contains the shell, viscera and part or all of the flesh. It should contain at least 25 per cent protein.

Shrimp Meal is prepared from the undecomposed waste of the shrimp industry and contains the head, hull and/or the whole shrimp.

Milk Products

Evaporated Buttermilk Feed, Concentrated Buttermilk Feed, Condensed Buttermilk Feed, is the product resulting from the removal of a considerable portion of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added excepting such as are permitted and necessary in the manufacture of butter. It contains not less than 27% of total solids, not less than 2% of butterfat, and not more than .14% ash for each per cent of solids. This definition does not prohibit the use of a distinctive trade name, provided it is followed by one of the names given.

Dried Skimmed Milk (Feeding) is the product resulting from the removal of water from clean, sound skimmed milk. It contains not more than 8 per cent moisture.

Condensed Skimmed Milk (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound skimmed milk. It contains not less than 27 per cent total solids.

Oat Products

Oat Groats are the kernels of the oat.

Oat Hulls are the outer coverings of the oat.

Oat Middlings are the floury portions of the oat groat obtained in the milling of rolled oats.

Oat Shorts are the covering of the oat grain lying immediately inside the hull, being a fuzzy material carrying with it considerable portions of the fine floury part of the groat obtained in the milling of rolled oats.

Clipped Oat By-products is the by-product obtained in the manufacture of clipped oats. It may contain the light chaffy material broken from the end of the hulls, empty hulls, light immature oats and dust. It must not contain an excessive amount of oat hulls.

Peanut Products

Peanut Oil Cake is the residue after the extraction of part of the oil by pressure or solvents from peanut kernels.

Peanut Oil Meal is ground peanut oil cake.

Unhulled Peanut Oil Feed is the ground residue obtained after extraction of part of the oil from whole peanuts, and the ingredients shall be designated as **Peanut Meal and Hulls.**

Rice Products

Rice Bran is the pericarp or bran layer of the rice, with only such quantity of hull fragments as is unavoidable in the regular milling of rice.

Rice Hulls are the outer coverings of the rice.

Rice Polish is the finely powdered material obtained in polishing the kernel.

Rice Meal is ground brown rice or ground rice after the hull has been removed.

Ground Rough Rice is ground rice from which the hull has not been removed or ground paddy rice.

Rice Stone Bran is the siftings from the materials secured in removing hulls from rice and contains rice germs, broken rice and some rice hulls.

Rice Huller Bran is a product secured by the huller and comes from brown rice and consists mostly of the bran and germs.

Rye Products

Rye Bran is the course outer covering of the rye kernel as separated from the cleaned and scoured rye.

Rye Feed, a by-product obtained in the usual process of the milling of rye flour from cleaned and scoured rye grain, consists principally of the mill-run of the outer covering of the rye grain and germ with small quantities of flour and aleurone.

Rye Red Dog, a by-product obtained in the usual process of the milling of rye flour, consists principally of aleurone with small quantities of flour and fine bran particles and shall not contain more than 3.5 per cent crude fiber.

Rye Low Grade Feed Flour consists principally of dark rye flour and small quantities of aleurone and fine bran particles and shall not contain more than 1.5 per cent crude fiber.

Rye Middlings consists of rye feed and rye red dog combined in the proportions obtained in the usual process of milling rye flour.

Rye Flour Middlings consists of rye feed, rye red dog and pure dark rye flour combined in the proportions obtained in the milling of rye flour and shall not contain more than 5 per cent crude fiber.

Velvet Bean Products

Velvet Bean Meal is ground velvet beans containing only an unavoidable trace of hulls or pods.

Ground Velvet Bean and Pod is the product derived by grinding velvet beans "in the pod." It contains no additional pods or other materials.

Wheat Products

Wheat Bran is the course outer covering of the wheat kernel as separated from cleaned and scoured wheat in the usual process of commercial milling.

Standard Middlings consists mostly of fine particles of bran, germ and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and shall not contain more than 9.5 per cent crude fiber.

Flour Middlings shall consist of standard middlings and red dog flour combined in the proportions obtained in the usual process of milling and shall not contain more than 6.0 per cent crude fiber.

Wheat Red Dog, a by-product obtained in the usual commercial process of flour milling, consists principally of aleurone with small quantities of flour and fine bran particles and shall not contain more than 4.0 per cent crude fiber.

Wheat Low Grade Feed Flour, a by-product obtained in the usual commercial process of flour milling, consists principally of flour with small quantities of aleurone and fine bran particles and shall not contain more than 1.5 per cent crude fiber.

Wheat Bran and Standard Middlings consists of the two commodities as defined above, mixed in the proportions obtained in the usual process of commercial milling.

Hard Wheat Mixed Feed (Mill-run wheat feed) consists of pure wheat bran and flour middlings combined in the proportions obtained in the usual process of commercial milling. This product shall not contain more than 9.5 per cent crude fiber.

Brown Shorts (Red Shorts) consists mostly of the fine particles of bran, germ and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and shall not contain more than 7.5 per cent crude fiber.

Gray Shorts (Gray Middlings or Total Shorts) consists of the fine particles of the outer bran, the inner bran or bee-wing bran, the germ and the offal or fibrous materials obtained from the "tail of the mill." This product must be obtained in the usual process of commercial milling and shall not contain more than 6.0 per cent crude fiber.

White Shorts or White Middlings consists of a small portion of the fine bran particles and the germ and a large portion of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual process of flour milling and shall not contain more than 3.5 per cent crude fiber.

Wheat Mixed Feed (Mill-run wheat feed) consists of pure wheat bran and the gray or total shorts combined in the proportions obtained in the usual process of commercial milling. This product shall not contain more than 8.5 per cent crude fiber.

Screenings consists of the smaller imperfect grains, weed seeds, and other foreign materials, having feeding value, separated in cleaning the grain.

Scourings consists of such portions of the cuticle, brush, white caps, dust, smut and other materials as are separated from the grain in the usual commercial process of scouring.

(NOTE) If to any of the wheat or rye by-products feeds there should be added screenings or scourings—as above defined, either ground or unground, bolted or unbolted, such bran shall be so registered, labeled and sold as clearly to indicate this fact. The word "Screenings" or "Scourings" as the case may be, shall appear as part of the name or brand and shall be printed in the same size and face of type as the remainder of the brand name. When the word "Screenings" appears it is not necessary to show also on the labeling the word "Scourings."

Mineral Feeds

Mixed feed containing both feed and more than 5 per cent of mineral ingredients requires, in addition to the usual declaration of the chemical feed analysis, a declaration of each ingredient contained therein and the minimum percentages of Calcium (CaO), phosphorus (P_2O_5), iodine (I), and the maximum percentage of salt ($NaCl$), if same is added. If minerals predominate in the mixture, the usual declaration of the chemical feed analysis, with the exception of protein, may be omitted.

Mineral feeds containing no organic ingredient do not require the usual chemical feed guarantee, but do require a declaration of each ingredient contained therein and the minimum percentage of calcium (CaO), phosphorus (P_2O_5), iodine (I), and the maximum percentage of salt ($NaCl$) if same are present.

That the mineral ingredients be stated in the common English terms, if any such terms exist.

It being impossible to classify separately the drug ingredients and the mineral ingredients, be it resolved:

(1) That all mixtures containing mineral ingredients generally regarded as dietary factors essential for the normal nutrition of animals and which are sold or represented for the primary purpose of supplying these minerals as additions to rations in which these same mineral factors may be deficient, be classified as mineral feeds.

(2) That all other preparations which are sold or represented primarily for the cure, mitigation or prevention of disease be classified by this association as drugs, medicines or specifics.

Miscellaneous Products

Dried Beet Pulp is the dried residue from sugar beets which have been cleaned and freed from crown, leaves and sand, and which have been extracted in the process of manufacturing sugar.

Cocoanut Oil Meal or "Copra Oil Meal" is the ground residue from the extraction of part of the oil from the dried meat of the cocoanut.

Ivory Nut Meal is the ground waste material resulting from the manufacture of buttons and similar articles from the vegetable ivory nut.

Processed Garbage is composed of animal and vegetable waste from garbage collected sufficiently often that harmful decomposition has not set in and is separated from material such as crockery, glass, or similar material. Its odor must not be suggestive of the presence of decomposition and it must contain less than one per cent of glass. None of it shall contain knife like or needle like particles, and providing further, that the maximum percentage of glass be stated on the label when present in excess of one-fifth of one per cent.

Palm Kernel Oil Meal is the ground residue from the extraction of part of the oil by pressure or solvents from the kernel of the fruit of Elaeis guineensis or Elaeis malanococco.

TENTATIVE DEFINITIONS

Table Scrap Meal is the properly cooked dried and ground residue resulting from freshly collected hotel and house garbage from which all metal, crockery, glass, and other foreign material has been removed except in such traces as may unavoidably occur in good factory practice. The finished product shall not be suggestive of material decomposition in odor. It shall not contain any sharp, needle pointed pieces of glass and shall not contain more than one-fifth of one per cent of finely ground glass or dull particles of glass.

Whole Pressed Cottonseed, Prime Quality, is the product resulting from subjecting the whole, sound, mature, clean, undecorticated cottonseed to pressure for the extraction of oil, and includes the entire cottonseed less the oil extracted and the lint removed. It shall be designated and sold according to its protein content.

Ground, Whole Pressed Cottonseed, Prime Quality, is whole pressed cottonseed, ground. It shall be designated and sold occording to its protein content.

Milk Products

Condensed Soured Skimmed Milk (Feeding) is the product resulting from the removal of a considerable portion of water from the clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not less than 27 per cent total solids.

Dried Buttermilk Feed is the product resulting from the removal of water from clean, sound buttermilk derived from natural cream, to which no foreign substances have been added, excepting such as are necessary and permitted in the manufacture of butter. It contains not more than 8 per cent of moisture, not more than 13 per cent of mineral matter (ash), and not less than 6 per cent butterfat.

Milk Sugar Feed is the by-product from the manufacture of cheese, containing at least 65 per cent lactose (milk sugar).

Corn Products

Corn Chop, Ground Corn or Cracked Corn is the entire product made by grinding, cutting or chopping the grains of Indian corn, and may be fine, medium, or coarse and must be neither weevilly, rancid nor musty, and shall not contain more than 4 per cent of foreign material.

Screened Corn Chop, Screened Ground Corn, or Screened Cracked Corn is the coarse portion of corn chop, ground corn or cracked corn from which most of the fine particles have been removed, and must be cool, neither weevilly, rancid nor musty, and shall not contain more than 4 per cent of foreign material.

Corn Meal (Feeding) is finely ground, unbolted corn.

Corn Bran is the outer coating of the corn kernel, with little or no starchy part of germ, and must be cool, neither weevilly, rancid nor musty.

Corn Feed Meal is the fine siftings obtained in the manufacture of screened corn chop, screened ground corn or screened cracked corn, with or without its aspiration products added, and must be cool, neither weevilly, rancid nor musty.

Corn Grits, Hominy Grits are the fine or medium sized, hard flinty portions of Indian corn containing little or no bran or germ.

Corn Screenings are the small, light grains of corn, parts of grains of corn and/or other cereals, and other materials having feeding value, obtained by screening shelled corn, excluding sand, dirt and other similar inert materials.

Oat Products

Oat Chop, Ground Oats, Pulverized Oats, Crushed Oats and Crimped Oats consists of the entire product made by grinding, chopping, cutting, crushing or crimping oats.

Oat Groats are the kernels produced from cleaned and dried oats in the process of manufacturing oat meal.

Hulled Oats, Undried Oat Groats are the kernels produced from the undried grain in the process of hulling oats.

Oat Meal, Ground Oat Groats is the product produced by cutting, cracking or grinding oat groats.

Rolled Oat Groats (Rolled Oats) is the product obtained in the process of rolling oat groats.

Oat Mill Feed is the by-product produced in the manufacture of oat groats and consists of oat hulls, oat shorts and oat middlings.

TABLE II—ESTIMATED SALES OF COMMERCIAL FEEDING STUFFS IN INDIANA

Kind of Feed	Estimated Tons			Estimated Retail Values, Dollars	
	1928	1929	1930	1929	1930
Alfalfa meal and leaf meal	2,625	2,657	3,063	129,130	135,997
Animal by-products (tankage, meat scrap, etc.)	25,812	26,094	27,750	1,823,971	1,709,400

COMMERCIAL FERTILIZERS

Fertilized   Unfertilized

Fertilizer Response on Wheat

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular gives a detailed report of the commercial fertilizer sold in Indiana for the year 1930. Table X reports the standing and individual record of every manufacturer responsible for the sale of fertilizer in Indiana from whose goods samples were taken.

Table II shows the tonnages of the analyses for which there is the most demand. The sales of 2-12-6 as in previous years are still far above any other analysis. Manufacturers report the sale of more than 89,000 tons as compared to about 79,000 tons of this analysis as calculated from tag sales.

There were 192,792 tons of high grade mixed fertilizer and only 5,001 tons of low and medium grade mixed fertilizer sold in Indiana last year.

The average content of actual plant food in all of the fertilizers sold in 1930 was 517 pounds per ton. The average analysis was 1.9% total nitrogen, 15.4% available phosphoric acid and 6.7% water soluble potash.

The sale of gross tons in 1930 was below that of 1929. The total number of pounds of available P_2O_5 was higher while the number of pounds of nitrogen and potash were somewhat lower than 1929.

Purchasers of Commercial Fertilizer for the Fall of 1931 and the Spring of 1932 should read the paragraph entitled "SPECIALS" on page 5 of this circular.

COMMERCIAL FERTILIZERS

H. R. Kraybill, *State Chemist*

. S. Roberts O. W. Ford L. E. Horat

M. H. Thornton

It is estimated that 219,684 tons of commercial fertilizer with a retail value of $8,521,905 were sold in Indiana in 1930. Inspectors from the State Chemist department drew 1421 official samples, representing one sample for every 147 tons sold. Of these samples 1320 were equal to or above the value in guarantee, 89 were within 10% of the value guaranteed and 10 were 10% or more below the guarantee in value. Eleven of the 897 samples which contained nitrogen showed inferior nitrogen of which six were dried manures and one was a tobacco product, which are inferior sources of nitrogen.

The Indiana Fertilizer Law is essentially a correct labeling law. It is not the intent of the law to determine what type of fertilizer may be sold. The law is designed to furnish the purchaser with certain information on the state tag that will enable him to decide whether or not the fertilizer is the type that will meet his needs. The Indiana state tag gives a statement of the percentages of total nitrogen, total or available phosphoric acid and water soluble potash. With this information available it is assumed that the purchaser will be able to judge whether the fertilizer offered for sale meets his requirements. In order that the law may be effective in accomplishing its purpose it is necessary that the consumer understand the meaning of the information on the state tag.

The fertilizer law is designed to protect the honest and efficient fertilizer manufacturer, dealer and agent as well as the consumer. Full cooperation on the part of the manufacturer, dealer, agent and consumer is necessary in order to accomplish the purpose of the law.

A copy of the full text of the law will be sent to persons making requests for the same to the State Chemist, Purdue University Agricultural Experiment Station, Lafayette, Indiana.

REFUNDS

Previous to 1930 most of the refunds have been due to deficiencies in potash but this year they were fairly well distributed between nitrogen, phosphoric acid and potash. A number of the phosphoric acid deficiencies have no doubt been due to reversion caused by the use of anhydrous ammonia. There is reason to believe that most of the fertilizer companies now doing business in Indiana are trying to maintain their guarantees.

When deficiencies in analysis amounting to $1.00 per ton or more as calculated from the wholesale price on raw materials are found refunds are calculated and indicated on the report of the analysis sent to the manufacturer and purchaser. Refunds are calculated on mixed fertilizers when one ingredient is deficient to the extent of $1.00 per ton regardless of the excess of other ingredients. Very frequently the excess value of one ingredient does not compensate for the deficiency of another in as much as the plant foods, nitrogen, available phosphoric acid and potash have specific functions to perform in plant production.

All refunds are required to be distributed to the consumer and receipts for same must be filed with the State Chemist.

A refund paid by the manufacturer to the consumer does not remove the violation of the law but it indicates his good intentions to correct the violation in so far as possible. The payment of these refunds, however, does not nullify the right of anyone in the state to call cases of deficiencies of analysis to the attention of prosecuting attorneys.

Refunds amounting to $920.09 were paid by 23 manufacturers on 85 shipments of fertilizer in 1930.

MANUFACTURERS

Any material used for manuring purposes except barnyard manure, marl, lime, wood ashes and plaster, must be registered with the State Chemist and properly tagged with the official state tag or label before it is offered or exposed for sale. A tag is good for 200 pounds but each package regardless of its weight must have attached to it a tag or label before it is offered or exposed for sale. Bulk shipments must be accompanied by sufficient tags or labels to cover the total weight of the shipment.

Manufacturers make themselves as well as their agents liable to prosecution when they ship untagged fertilizer. Several cases of this nature in 1930 were called to the attention of the prosecutor with the result that the manufacturer paid the usual fine of $50 and costs for the first offense.

Manufacturers should not ship untagged fertilizers with a view to furnishing the state tags later by mail. Experience has shown hat when this is done it is difficult to avoid the sale of untagged ertilizer. The State Chemist has no authority to grant permission o a manufacturer to ship unlabeled fertilizer.

AGENTS, DEALERS, DISTRIBUTORS

The Indiana Fertilizer Law recognizes only the State Chemist ags or labels bearing the facsimile signature of the State Chemist (see reproduction page 20). The State Chemist label is always rinted and any alteration thereon constitutes a violation of the aw. Do not accept, offer or expose for sale, sell, deliver, distribute r have in your possession any quantity of commercial fertilizer hat is not tagged with the State Chemist label.

Since local agents are directly responsible for the fertilizer they ffer for sale, they should protect themselves by a clause in their ontract wherein the manufacturer agrees to assume all responsibility for all fines or refunds in cases where the fertilizer fails to neet the requirements of the law.

CONSUMERS

Refuse to accept any fertilizer that is not correctly labeled. Be guided by the analysis rather than the brand name. Consult the nnual fertilizer circular of this department and buy from those ompanies whose records of inspection show that they are shipping agged fertilizer and are maintaining their guarantees.

SPECIALS

Frequently cases of trade misrepresentation are called to the ttention of the State Chemist. It should be remembered in this onnection that the Indiana Fertilizer Law is essentially a correct abeling law and that the fact that a State Chemist tag is attached o the fertilizer is no assurance that the fertilizer is a good fertilizer. The presence of the State Chemist tag shows that the manufacturer has complied with the fertilizer law by registering the material and attaching to it an Indiana state tag on which is shown he manufacturer's guaranteed analysis. A poor fertilizer may be old under the law so long as it is correctly labeled. In order to btain full benefit of the law it is necessary for the consumer to onsider the information given on the state tag.

Recently mixtures of rock phosphate and potash and mixtures f rock phosphate and potash and nitrogen salts have been placed n the market. Typical examples of these are as follows:

1. Mixtures of rock phosphate and potash in which the guarantees are 19.0% total phosphoric acid and 10.0% water solubl potash; 24.0% total phosphoric acid and 12.0% water solubl potash, etc.
2. Mixtures of rock phosphate and potash and nitrogen salts i which the guarantees are as follows: 2.0% total nitroger 24.0% total phosphoric acid and 6.0% water soluble potash 4.0% total nitrogen, 22.0% total phosphoric acid and 6.0 water soluble potash.

These mixtures have been referred to in unfair trade practice as 0-19-19, 0-24-12, 2-24-6 and 4-22-6 respectively. In this connection the consumer should keep in mind the distinction betwee total phosphoric acid and available phosphoric acid. A fertilizer o the grade 0-24-12 contains 24% available phosphoric acid. Thes mixtures made from rock phosphate contain very low amounts o available phosphoric acid. The value of the total phosphoric aci in one of these rock phosphate mixtures is from 40 to 50 cents unit while the value of the available phosphoric acid is $1.20 pe unit.

Another misrepresentation that is frequently made is the implication that a fertilizer that shows the following analysis, 2.0 total nitrogen, 8.0% available phosphoric acid, 8.0% insoluble phosphoric acid and 2.0% water soluble potash is a 2-16-2 fertilizer. Th former fertilizer is not worth as much money as a 2-16-2 fertilize The 2-16-2 fertilizer contains 16.0% available phosphoric aci while the other fertilizer contains only 8.0% available phosphori acid.

It is important for the consumer to read the tag carefully an to be guided by the analysis rather than by the brand name o claims of the agent.

A fair and comparatively simple way to evaluate different fertilizers is to calculate the value of the ingredients of each accordin to the same standard. Using $3.00 per unit for nitrogen, $1.00 pe unit for potash and $1.20 per unit for available phosphoric acid an $0.40 per unit for insoluble phosphoric acid which has about th same value as the total phosphoric acid in raw rock phosphate th fertilizer containing 2.0% nitrogen, 8.0% available phosphoric acid 8.0% insoluble phosphoric acid and 2.0% water soluble potash woul be worth $22.40 as compared to $28.80 for the regular 2-16-2 fertilizer.

Using the same values for plant foods we find that a rock phosphate mixture containing 4.0% nitrogen, 24.0% total P_2O_5 and 6.0% water soluble potash has a value of $27.60 per ton while a regular 4-24-6 fertilizer has a value of $46.80 per ton. The method of calculation is as follows:

FOR ROCK PHOSPHATE MIXTURE

4 units of nitrogen	$12.00
24 units total P_2O_5 from rock phosphate	9.60
6 units water soluble potash	6.00
Total	$27.60

FOR THE REGULAR 4-24-6

4 units of nitrogen	$12.00
24 units of available P_2O_5	28.80
6 units of water soluble potash	6.00
Total	$46.80

In the group of comparisons that follow the above values were applied to various analyses and this value was then inserted between the high and low retail price as found on the open Indiana fertilizer market.

Analysis	Minimum Retail Price	Comparative Value	Maximum Retail Price
2-12-6	$27.90	$26.40	$41.65
4-24-12	51.50	52.80	71.75
2-16-8	37.15	33.20	43.20
1-8-4	24.20	16.60	31.50
2-12-2	27.85	22.40	34.92
4-24-4	48.50	44.80	57.00
2-8-2	28.70	17.60	37.05
4-16-4	34.25	35.20	47.45
2-16-2	32.00	27.20	35.70
*2-8-8-2	36.25	20.80	36.85
*0-6-6-10	35.55	17.20	37.65
0-14-6	26.90	22.80	33.25
0-28-12	57.20	45.60	65.00
0-12-12	32.10	26.40	37.00
0-24-24	60.80	52.80	65.00
0-10-10	26.00	22.00	33.05
0-20-20	44.00	44.00	56.85

* The above so called "2-8-8-2" and "0-6-6-10" are no longer received for registration as such. See the explanation of cases of this kind under specials, page — of this circular.

MEANING OF ANALYSIS

As recognized under the Indiana Fertilizer Law there are only three valuable fertilizer elements, nitrogen, phosphorus and potassium. These three elements do not occur in a free state but are always combined as chemical compounds. This facilitates the han ling of them in commercial fertilizer mixtures. A brief discussi of these, their value and availability as plant food, is given in t following paragraphs.

Nitrogen.

In 1881 when the Indiana Fertilizer Law was passed the pri cipal source of nitrogen was of an organic nature. The nitrog was derived largely from such products as dried blood, bone, tan age and slaughter house by-products, garbage tankage, cottonse meal, castor pomace, tobacco stems, manure sweepings and dri peat. Although there was little water soluble nitrogen in the abo products all carry a good source of nitrogen with the exception garbage tankage, manure sweepings, tobacco stems and dried pea Since 1881 most of the bone products have been diverted into t mixed feed channels and water soluble forms of nitrogen have tak their place in fertilizer mixtures. Today we find that most of trogen carrying fertilizers have better than 80% of their nitrog content in some water soluble form.

A few of the sources of water soluble forms of nitrogen are follows: nitrate of soda (natural and synthetic), ammonia su phate, cal urea, cal-nitro, urea and calcium nitrate.

Since water soluble forms of nitrogen are considered as bei ready available for plant growth, we class a fertilizer that h 60% of its guaranteed nitrogen as water soluble as satisfactory.

If less than 60% of its guaranteed nitrogen is water soluble th the availability of the insoluble organic nitrogen is determined the alkaline permanganate method. In this case if the active wat insoluble nitrogen is equal to or greater than the inactive the trogen is classed as satisfactory. If less than half of the insolub nitrogen is active the nitrogen is classed as inferior.

In case the nitrogen is found to be inferior the inactive wat insoluble nitrogen appears in heavy type in Table X. Manures a garbage tankages that have not been acidulated show an inferi quality of nitrogen.

This is not the fault of the manufacturer when they are sold manure and garbage tankage. The past year's inspection had sev samples showing an inferior source of nitrogen, of which numbe one was a manure. This is noted and set forth in Table X of th Circular.

Phosphoric Acid.

The phosphorus in the fertilizer is linked up as chemical compounds with calcium, iron and aluminum. It may be as mono-, di- or tricalcium phosphate.

As monocalcium phosphate $CaH_4(PO_4)_2$ it is water soluble and readily available to plants for growth.

As dicalcium phosphate $Ca_2H_2(PO_4)_2$ it is water soluble in the soil solution and rendered available to plants for growth.

As tricalcium phosphate $Ca_3(PO_4)_2$ it is somewhat less available to plants.

As a complex tricalcium phosphate combined with fluorine and lime (raw rock phosphate) it is much less available to plants and becomes available only slowly in the soil.

The bulk of the fertilizer sold today contains mixtures of large amounts of mono and dicalcium phosphate and a slight amount of tricalcium phosphate. This is in contrast to the earlier years when most of the fertilizers used was bone where the phosphorus is present as tricalcium phosphate.

In acidulated goods the phosphorus is sold only on the available P_2O_5 content. This would be the sum of the soluble and reverted P_2O_5.

In bone and rock phosphate the phosphorus is sold only on the total P_2O_5 content. It is only fair to state, however, that about $^1/_3$ of the total P_2O_5 content of bone would show available by the neutral ammonium citrate method while rock phosphate would show only from two to four per cent by the same method.

Potash.

Potash, as the official label states, must be soluble in water, in which form it is considered directly available for plant use.

No difference in crop growth has been noted in American, French or German potash. Muriate of potash (KCl) being the cheapest has largely supplanted other potash salts for general crops.

STATE CHEMIST RULING

After January 1, 1929, no applications for registration of mixed fertilizers will be accepted except those that are guaranteed to contain minimum percentages of nitrogen, available phosphoric acid and water soluble potash, stated as whole numbers in the preceding order. Any numerals used on the bag or in advertising matter to describe the analysis of the fertilizers being offered for sale must be so arranged that the first numeral will be the minimum guaranteed percentage of nitrogen, the second numeral the minimum guaranteed percentage of available phosphoric acid and the third numeral the minimum guaranteed percentage of water soluble potash.

RULINGS ADOPTED BY A. O. A. C.

FERTILIZER GRADE

The grade of a fertilizer shall represent the minimum guarantee of its plant food expressed in terms of nitrogen, available phosphoric acid, and water soluble potash.

FERTILIZER FORMULA

The term fertilizer formula shall be interpreted as expressing the quantity and grade of the crude stock materials used in making a fertilizer mixture. For example: 800 pounds of 16 per cent acid phosphate, 800 pounds of 9-20 tankage, and 400 pounds of sulfate of potash-magnesia.

FERTILIZER ANALYSIS

The word analysis, as applied to fertilizers, shall designate the percentage composition of the product expressed in terms of nitrogen or ammonia, phosphoric acid, and potash in their various forms.

BRAND AND BRAND NAME

A brand is a term, design, or trade mark used in connection with one or several grades of fertilizers.

A brand name is a specific designation applied to an individual fertilizer.

INTERPRETATION OF BRAND NAME TO INCLUDE THE ANALYSIS OR GRADE OF FERTILIZER

The committee recommends and urges the practice of including the analysis or grade of fertilizer with the brand name, both by the manufacturer on sacks and in printed literature and by the control official in his reports and publications.

UNIT

A unit of plant food is twenty (20) pounds, or one per cent (1%) of a ton.

MEANING OF TERM "FINELY GROUND"

The term finely ground in the definition of basic phosphate slag shall refer to actual size of particles as determined by the use of standard sieves, as follows: seventy per cent (70%) or more should pass a 100-, and ninety per cent (90%) or more should pass a 50-mesh sieve.

"LIME" AS APPLIED TO FERTILIZERS

The term lime shall not be used in the registration, labeling, or guaranteeing of fertilizers or fertilizing materials unless the lime is in a form to neutralize soil acidity, such as the oxide, hydroxide, or carbonate, or equivalent magnesia compounds.

LEACHED WOOD ASHES

Leached wood ashes are defined as ashes resulting from burning unleached wood, but as having had part of their plant food removed by artificial means or by exposure to rains, snows, or other solvent.

UNLEACHED WOOD ASHES

Unleached wood ashes are ashes that result from burning unleached wood, that had had no part of their plant food removed, and that contain four per cent (4%) or more of water-soluble potash (K_2O).

ASHES FROM LEACHED WOOD

Ashes from leached wood are defined as unleached ashes resulting from burning wood that has been exposed to or digested in water or other liquid solvent, as in the extraction of dyes, so that a part of the plant food has been dissolved and removed.

DRIED PULVERIZED OR SHREDDED MANURES

Dried pulverized or shredded manures shall be only what the name indicates, and not mixtures of manures and other materials.

FORM OF NITROGEN IN CYANAMIDE

The nitrogen in calcium cyanamide shall be considered as being of organic nature.

KAINIT

Kainit is a potash salt containing potassium and sodium chlorides and sometimes sulfate of magnesia with not less than twelve per cent (12%) of potash (K_2O).

MANURE SALTS

Manure salts shall be understood to mean potash salts containing high percentages of chloride and from twenty per cent (20%) to thirty per cent (30%) of potash (K_2O). The term double manure salts should be discontinued.

NITRATE OF POTASH (COMMERCIAL POTASSIUM NITRATE)

Nitrate of potash is a salt containing not less than twelve per cent (12%) of nitrogen and forty-four per cent (44%) of potash (K_2O).

MURIATE OF POTASH (COMMERCIAL POTASSIUM CHLORIDE)

Muriate of potash is a potash salt containing not less than forty-eight per cent (48%) of potash (K_2O) chiefly as chloride.

SULFATE OF POTASH-MAGNESIA

Sulfate of potash-magnesia is a potash salt containing not less than twenty-five per cent (25%) of potash (K_2O), nor less than twenty-five per cent (25%) of sulfate of magnesia, and not more than two and five-tenths per cent (2.5%) of chlorine.

SULFATE OF POTASH (COMMERCIAL POTASSIUM SULFATE)

Sulfate of potash is a potash salt containing not less than forty-eight per cent (48%) of potash (K_2O) chiefly as sulfate, and not more than two and one-half per cent (2.5%) of chlorine.

MAXIMUM AMOUNT OF CHLORINE PERMISSIBLE IN FERTILIZERS IN WHICH THE POTASH IS CLAIMED AS SULFATE

The chlorine in mixed fertilizers in which the potash is claimed as sulfate shall not exceed five-tenths of one per cent (0.5%) more than what is called for in the minimum potash content based on the definition for sulfate of potash as formulated by the committee. Calculate as follows: 0.05 times the percentage of potash found plus 0.5.

DEFINITION OF PRODUCTS SECURED BY HEATING CALCIUM PHOSPHATE WITH ALKALI SALTS CONTAINING POTASH

These products are not potassium phosphate. They may be called non-acid phosphates with potash.

BASIC PHOSPHATE SLAG

Basic phosphate slag is a by-product in the manufacture of steel from phosphatic iron ores. The product shall be finely ground and shall contain no admixture of materials other than what results in the original process of manufacture. It shall contain not less than twelve per cent (12%) of total phosphoric acid (P_2O_5), not less than eighty per cent (80%) of which shall be soluble in two per cent (2%) citric acid solution according to the Wagner method of analysis. Any other phosphate slag not conforming to this definition shall be designated low grade.

DISSOLVED BONE

Dissolved bone is defined as a ground bone or bone meal that has been treated with sulfuric acid.

NITRATE OF SODA (COMMERCIAL SODIUM NITRATE)

Nitrate of soda is commercial sodium nitrate containing not less than fifteen per cent (15%) of nitrogen, chiefly as sodium nitrate.

DRIED BLOOD

Dried blood is the collected blood of slaughtered animals, dried and ground and containing not less than twelve per cent (12%) of nitrogen in organic forms.

GROUND RAW BONE

Ground raw bone is a product resulting from drying and grinding animal bones that have not been previously steamed under pressure.

GROUND STEAMED BONE

Ground steamed bone is a product resulting from grinding animal bones that have been previously steamed under pressure.

TANKAGE

The term tankage (without qualification) shall be restricted to meat and bone tankage derived from the rendered, dried and ground by-products from slaughter of animals, or from carcasses of animals that have died otherwise than by slaughter.

FISH TANKAGE, FISH SCRAP, DRY GROUND FISH, FISH MEAL FERTILIZER GRADE

Fish tankage, fish scrap, dry ground fish, fish meal fertilizer grade is the dried ground product derived from rendered or unrendered fish.

GARBAGE TANKAGE

Garbage tankage is the rendered, dried, and ground product derived from waste household food materials.

HOOF AND HORN MEAL

Hoof and horn meal is a product resulting from the processing, drying, and grinding of hoofs and horns.

SUPERPHOSPHATE

Superphosphate is the product resulting from mixing rock phosphate and sulfuric acid and/or phosphoric acid. The grade should always be used as a prefix to the name.

Example: 16% Superphosphate.

It is recommended that the use of the term "Acid Phosphate" be discontinued.

CRUDE, INERT, OR SLOW-ACTING NITROGENOUS MATERIALS

Crude, inert, or slow-acting nitrogenous materials are unprocessed organic substances relatively high in nitrogen but having a very low value as plant food and showing a low activity by both the alkaline and neutral permanganate methods (below fifty per cent (50%) and eighty per cent (80%) respectively).

ACTIVITY OF WATER-SOLUBLE NITROGEN IN MIXED FERTILIZERS

The alkaline and neutral permanganate methods distinguish between the better and the poorer sources of water-soluble nitrogen, and do not show the percentage availability of the material. The available nitrogen of any product can be measured only after carefully conducted vegetation experiments.

(a) The methods shall be used on mixed fertilizers containing water-soluble nitrogen amounting to three-tenths of one per cent (0.3%) or more of the weight of the material. In the event of a total nitrogen exceeding the minimum guarantee, accompanied by a low activity of the insoluble nitrogen, the over-run may be taken into consideration in determining the classification of the water-insoluble nitrogen.

(b) The water-insoluble nitrogen in mixed fertilizers showing an activity below fifty per cent (50%) by the alkaline method and also below eighty per cent (80%) by the neutral method shall be classed as inferior. This necessitates the use of both methods before classifying as inferior.

CLASSIFIED FERTILIZER SALES SINCE 1883

The changes in the sales of fertilizing materials have kept in line with the development of both the feed and fertilizer industries. In the early years the fertilizer consisted almost entirely of bone and other animal products. Today these products have been diverted largely into the feed channels and replaced by superphosphates and nitrogen salts. Additions of potash salts to the superphosphate and nitrogen salt mixtures and various combinations of these ingredients have replaced almost entirely the tonnages that were formerly sold under the general classification of animal by-products.

The following table sets forth the changes that have occurred since the Indiana Fertilizer Law was passed in 1881.

TABLE I. Classified Fertilizer Sales Since 1883

Year	Total Tons	Tons Nitrogen Salts	Tons Potash Salts	Tons Super-Phosphate	Tons Bone	Tons Raw Rock Phosphate	Tons Phosphate Potash	Tons Ammoni-ated Super-Phosphate	Tons Complete
1883........	8,000	....	....	....	8,000	....	....	....	....
1888	10,000	....	....	‡	10,000	....	‡	‡	‡
1893........	38,000	....	....	1,000	14,000	....	1,000	4,000	18,000
1895........	45,000	....	....	1,000	15,000	....	1,000	3,800	20,300
1897........	49,400	....	....	7,200	13,900	50	1,500	5,200	21,450

* Largely Nitrate of Soda.
† Nitrate of Soda and Ammonium Sulphate.
‡ Light Sales.

WHY THE MULTIPLICITY OF ANALYSES

The question has often been asked "Why are so many different analyses offered for sale?" It is universally agreed that this practice is both costly and useless. By following the recommendation of the Purdue University Agricultural Experiment Station (Circular 162 Fertilizer for Indiana Soils and Crops) the number of the analyses and the cost of the same could be reduced.

While the analyses listed below are not all recognized recommendations, it shows that at least 75 per cent of those that are offered for sale could be eliminated without affecting the total tonnage materially.

TABLE II. Showing tons sold under 33 analyses for past seven years—calculated from tag sales. A glance at the last four columns shows the difference in tons calculated by tag sales and that reported by Manufacturers as being sold under these 33 analyses for 1929 and 1930.

ANALYSIS	Year 1924	Year 1925	Year 1926	Year 1927	Year 1928	Year 1929	Rept. by Mfrs. Year 1929	Year 1930	Rept. by Mfrs. Year 1930

D. Bone Products (Steam and Raw Bone—Fertilizer Tankages)—1,465.9.
E. Raw Rock Phosphate—543.0.
F. Miscellaneous—1,269.1.
G. Unclassified (Made up of Superphosphates reported sold in bulk but no definite analysis reported)—1,035.2.

Summary—

1. Total tons reported—246,009.1.
2. Tag sales from firms not reporting—1,469.0.
3. Total tonnage based on reports (Items 1 and 2)—247,478.1.
4. Total tonnage from tag sales—219,653.0.

EXPLANATION OF TABLES

Buyers of fertilizer for the Fall of 1931 and the Spring of 1932 should read this circular before buying.

A brief study of the column headings will aid in a better understanding of the various tables appearing in this circular.

Figures appearing in heavy type indicate that the analysis failed to meet the guarantee of the manufacturer. There is one exception to this rule, namely, heavy type in the third column of Table XI indicates that inferior nitrogen was found in the sample.

The footnotes at the bottom of each page explain whether refund was made, amount of shipment returned to manufacturer, etc.

In case of deficient samples manufacturers were given ten days' advance notice and opportunity to secure a portion of our sample for review of our results by their chemists.

In comparing the standing of the manufacturers, Table X should always be used in connection with Table XI.

The following table (III) sets forth the total tonnage, retail value, cost per ton, pounds of actual plant food per ton and the cost per pound of plant food for the past 11 years.

TABLE III

Year	Tonnage per year	Retail Value Dollars	Cost per ton Dollars	Pounds per ton actual plant food	Cost per pound Plant Food Cents
1920	231,791	8,637,055	37.26	328	0.114
1921	187,923	6,031,305	32.10	354	0.091
1922	209,310	5,730,536	27.40	372	0.074
1923	198,581	6,293,033	31.70	412	0.077
1924	192,417	6,479,605	33.68	446	0.075
1925	226,148	8,253,670	36.50	458	0.079
1926	228,280	8,464,607	37.22	452	0.082
1927	240,498	8,998,412	37.41	444	0.084
1928	221,082	8,254,591	37.33	444	0.084
1929	291,193	11,327,868	38.89	417	0.094
1930	219,684	8,521,905	38.79	518	0.075

Since 1920 there has been a marked reduction in the sales of low and medium grade mixed fertilizers and a corresponding increase of high grade fertilizers.

The actual plant food per ton in pounds was higher in 1930 than it has been any year since the same has been calculated. The fact that this was true in spite of the large reduction in the total tonnage only strengthens the statement that the sales of high grade fertilizers are still increasing.

The comparison of mixed fertilizer sales for the past eleven years follows:

TABLE IV

Mixed Fertilizer	1920 tons	1921 tons	1922 tons	1923 tons	1924 tons	1925 tons	1926 tons	1927 tons	1928 tons	1929 tons	1930 tons
Low and Medium Grade....	84,760	55,887	43,459	25,773	21,759	17,989	16,892	13,722	6,562	10,506	5,001
High Grade.	57,881	59,809	89,527	104,990	98,832	127,928	146,177	179,695	179,597	248,566	192,792

The following table (V) shows the comparison of tonnage sales for the past eleven years with the amount of actual plant food in tons per year and with the retail value per year.

TABLE V

Year	Fertilizer tons	Tons of nitrogen, phosphoric acid and potash	Cost Indiana farmers
1920	231,791	37,961.57	$8,637,055.00
1921	187,923	33,170.08	6,031,305.00
1922	209,310	39,026.25	5,730,536.00
1923	198,581	40,929.03	6,293,033.00

* Corrected figures for 1924.

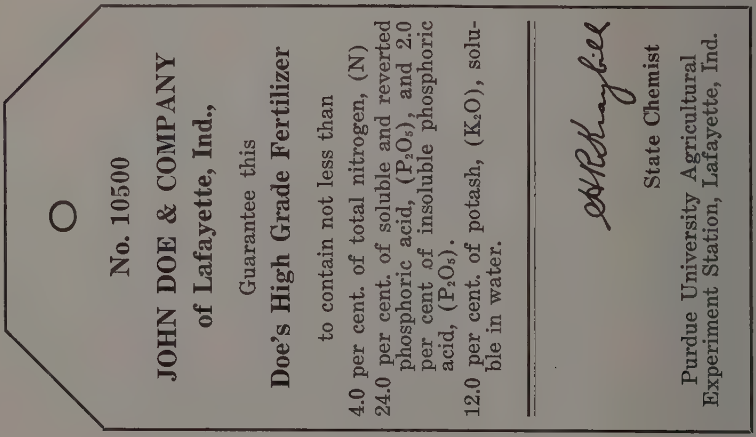
TABLE VII. Summary of Inspection for the Past Twenty-nine Years

Year	Number of samples reported	Number equal to guarantee in every particular	Number equal in value to guarantee	Number within 10 per cent of value of guarantee	Number not within 10 per cent of value of guarantee
1902	679	335	564	93	22
1903	674	286	492	139	43
1904	643	248	451	148	44
1905	734	312	528	158	48
1906	879	374	642	176	61
1907	793	265	481	210	102
1908	901	391	683	171	47
1909	969	417	720	215	34
1910	1,118	441	834	242	42
1911	1,095	527	896	180	19
1912	1,220	636	1,034	175	11
1913	1,204	714	1,021	178	5
1914	1,396	727	1,152	239	5
1915	1,368	684	1,145	214	9
1916	1,367	870	1,183	168	16
1917	919	622	830	76	13
1918	1,285	888	1,142	121	22
1919	1,401[1]	936	1,227	141	32
1920	1,491[2]	944	1,267	188	27
1921	1,314	754	1,070	227	17
1922	1,216	812	1,071	132	13
1923	1,325	970	1,214	108	3
1924	1,439	1,072	1,340	94	5
1925	1,442	1,019	1,329	111	2
1926	1,225	798	1,033	183	9
1927	1,450	909	1,277	163	10
1928	1,437	865	1,283	144	9
1929	1,378	854	1,217	155	6
1930	1,421	1,090	1,320	89	10

[1] One sample not registered.
[2] Nine samples not registered.



No. 10500

JOHN DOE & COMPANY
of Lafayette, Ind.,

Guarantee this

Doe's High Grade Fertilizer

to contain not less than

4.0 per cent. of total nitrogen, (N)
24.0 per cent. of soluble and reverted phosphoric acid, (P_2O_5), and 2.0 per cent of insoluble phosphoric acid, (P_2O_5).
12.0 per cent. of potash, (K_2O), soluble in water.

HRKraybill
State Chemist

Purdue University Agricultural
Experiment Station, Lafayette, Ind.

LABELS

The only label recognized under the law is that bearing the facsimile signature of the State Chemist. (See reproduction.) The label as issued is always printed and contains all the facts required by law; any alteration thereon constitutes a violation of the law.

Label No. 10500 guarantees that each 100 pounds of fertilizer will contain at least 4.0 pounds of total nitrogen (N), 24.0 pounds of soluble and reverted phosphoric acid (P_2O_5), and 2.0 pounds of insoluble phosphoric acid (P_2O_5), and 12.0 pounds of water soluble potash (K_2O).

We hope that it will not again be necessary to file affidavits against agents for distributing unlabeled fertilizer. There can be no excuse for shipping unlabeled fertilizer. Agents receiving same should protect themselves by refusing to accept the car. Wire the manufacturer for official labels and write the State Chemist fully concerning the unlabeled shipment.

TABLE VIII—Fertilizer Tonnage and Estimated Retail Value, 1930

Class of Fertilizer	Spring 1930 tons	Fall 1930 tons	Total 1930 tons	Estimated 1930 Retail Value Dollars
1. Acid phosphate, 14% and less	63	813	876	$21,900.00
2. Acid phosphate, 16%	1,250	2,437	3,687	85,464.66
3. Acid phosphate, 18-20%	1,875	4,563	6,438	173,954.76
4. Acid phosphate above 20%	500	687	1,187	55,926.40
10. Acid phosphate and potash, 14-19 units	594	1,250	1,844	54,213.60
10a. Acid phosphate and potash above 20 units	24,469	8,344	32,813	1,217,034.17
11. Complete fertilizer (low)	469	750	1,219	40,470.38
12. Complete fertilizer (medium)	1,688	2,094	3,782	111,606.82
13. Complete fertilizer (high)	21,688	20,444	42,132	1,547,087.04
13a. Complete fertilizer above 20 units	70,047	45,956	116,003	4,802,524.20
14. Steamed bone	156	1,063	1,219	50,783.54
15. Raw bone	288	469	757	31,309.52
16. Tankage†	219	250	469	19,229.00
19. Rock phosphate, nitrogen salts, and potash salts (A)	31	....	31	1,280.30
20. Rock phosphate and potash salts (B)	63	63	126	5,342.40
21. Rock phosphate	625	875	1,500	17,085.00
22. Nitrogen salts*	2,500	450	2,950	165,318.00
23. Potash salts*	1,900	....	1,900	81,713.00
31. Miscellaneous (peat, dried manure, dried blood, garbage, tankage, etc.)	688	63	751	39,662.80
Total	129,113	90,571	219,684	$8,521,905.59

* Tonnage in these classes estimated on the 200-pound sack or 10 per ton. All other classes estimated on the 125-pound sack or 16 per ton.

† No samples taken. Value based on last year's prices.

(A) Mixture of rock phosphate, nitrogen, and potash salts.

(B) Mixture of rock phosphate and potash salts.

PRICES USED IN SECURING COMPARATIVE VALUE OF FERTILIZERS

These values are not for the purpose of fixing the commercial value of mixed fertilizers, but are for comparative purposes only. They are for use in comparing the value of inspection samples with manufacturers' guarantees, and can be used advantageously by fertilizer purchasers in calculating the relative values of various brands offered for sale by different manufacturers.

For use in determining the comparative values of fertilizer inspected in 1931, the following prices have been adopted:

	Per lb. cts.	Per unit or per cent, $
All fertilizers		
Nitrogen (N)	12.5	2.50
Potash (K_2O) Soluble in water	5.0	1.00
Soluble and reverted phosphoric acid (P_2O_5)	6.0	1.20
Mixed fertilizers containing nitrogen		
Insoluble phosphoric acid (P_2O_5)	2.0	0.40
Precipitated bone		
Available phosphoric acid (P_2O_5)	6.0	1.20
Insoluble phosphoric acid (P_2O_5)	5.0	1.00
Animal by-products, bone, tankage, etc.		
Total phosphoric acid (P_2O_5)	4.5	0.90
Basic slag		
Total phosphoric acid (P_2O_5)	4.5	0.90
Rock phosphate (floats) and low grade slag		
Total phosphoric acid (P_2O_5)	2.0	0.40
Mixed fertilizer, acid phosphate, etc., containing no nitrogen		
Insoluble phosphoric acid	.0	0.00

TABLE IX—Summary of Inspection on the Basis of Composition, Guaranteed, Found, and Retail Values

Class of Fertilizer	Number of Samples	Nitrogen (N), average per cent.		Available phosphoric acid (P_2O_5), average per cent.		Insoluble phosphoric acid (P_2O_5), average per cent.		Total phosphoric acid (P_2O_5), average per cent.		Potash (K_2O), soluble in water average per cent.		Comparative value per ton, dollars		Retail price per ton, average, dollars	Comparison, retail price and found comparative value per ton, dollars	Range in retail price per ton, dollars

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic was not determined.
Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

[71] Purchased from Princeton Canning Co.

[72] Sample received in the spring.

[73] Refund $13.44.

[74] Refund $2.70.

[75] Sample received in the spring.

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

[196] Refund $1.50.

[197] Purchased from Chas. Price.

[198] Sample to manufacturer. Refund $15.50.

[199] Refund $3.30.

[200] Sample to manufacturer. Refund $2.00.

[201] Refund $8.85.

[202] Refund $7.92.

[203] Sample received in the spring.

[204] Purchased from Lafayette Cooperative Elevator.

REPORT OF MOSES FELL ANNEX FARM

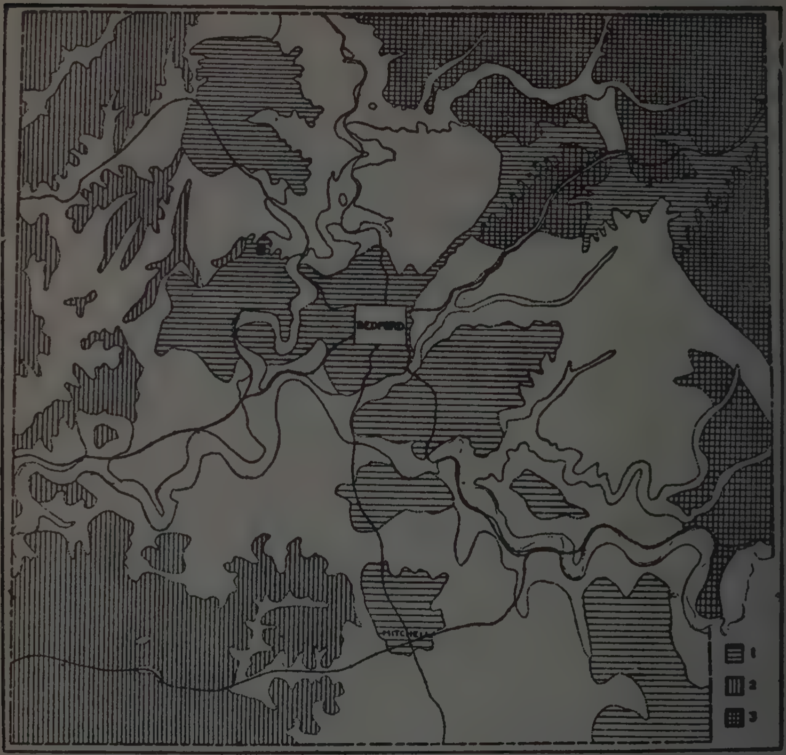
BEDFORD, INDIANA

JUNE 1931

UNIVERSITY OF ARIZONA
SEP 26 1931
LIBRARY

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

Map Showing Soil Types Similar to Experiment Field



Region	Principal Soil Characteristics
No. 1.	**Yellowish limestone land like Bedford experimental field.**
No. 2.	**Yellowish "freestone" land.**
No. 3.	**Like No. 1 on ridge tops and like No. 2 on lower slopes.**

The results of the Moses Fell Annex Farm can be applied to the greater part of Lawrence County and surrounding territory.

The soil survey made in this county in 1922 enabled the Department of Agronomy to classify the soils of this section and to indicate the types which can benefit most from the experimental work on this farm.

The results will apply to all similar land in the county, which is indicated by shading No. 1 on the map. They will also apply fully as well to the areas indicated by shading No. 2, and more or less fully to the areas indicated by shading No. 3 where the hilltops are like No. 1 and the lower slopes like No. 2.

Portions of the unshaded area would doubtless respond to similar treatments, but most of it does not need either lime or fertilizer to the same extent as the shaded areas.

REPORT OF MOSES FELL ANNEX FARM

JUNE, 1931

H. J. REED, Farm Director H. G. HALL, Superintendent

The drought of 1930 seriously affected the crops of the farm but the average results over a period of years show worthwhile returns from the best methods of soil management. The value of the most profitable methods of fertilization was emphasized by the severe conditions existing last summer.

The work of the farm has been expanded during the last year to give additional information on pertinent problems which interest the people of this vicinity. The livestock work has had additional attention and the sheep and lamb experiments were started. A herd of eight calves were imported from Canada to establish a foundation for the cooperative project with the Bureau of Animal Industry of the U. S. Department of Agriculture; the pasture work has been enlarged; the orchard has been carefully scraped

Governor Harry G. Leslie, P. R. Edgerton, member of the Board of Trustees of Purdue University, and Director J. H. Skinner were the principal speakers at the Annual Field Day, Moses Fell Annex Farm.

to make possible better codling moth control; parasites colonies have been started to aid in checking the attack of the oriental fruit worm; a deep well has been drilled to improve the water supply of the farm and many other improvements have been made to the equipment.

At the meeting last year on June 12 the new gateway was dedicated to honor Moses Fell Dunn for his services to agriculture through the bequest of this farm for experimental and demonstration purposes. President Elliott of Purdue University wrote Director Skinner as follows:

"You know how deeply I regret the circumstances that prevent me from attending the gateway dedication ceremony at the Moses Fell Farm on Thursday. This is to be an event of importance and I hope you will express for me and for the Trustees the satisfaction that the University has from the great service which is being performed by the Moses Fell Experimental Farm for the betterment of agriculture in Lawrence County, and indeed for the entire state.

"The gateway to be dedicated is intended to be a tribute to the memory of a generous and far-sighted man. Through the Farm which bears his name, Moses Fell Dunn has become an active citizen of the state for unnumbered generations. It is a part of his eternal life and influence.

"The memorial gateway is a useful structure. It is also a symbol that the road to the Farm is always open to those who know agriculture must know more each year if it is to be maintained in this rapidly competitive world."

In speaking further for the institution, Director J. H. Skinner said:

"A genuine interest in agriculture and country life; and faith and confidence in the people of Lawrence County and southern Indiana; a generous spirit and a desire to enrich the lives of people whom he loved, prompted this man—Hon. Moses Fell Dunn to give this farm, known as The Moses Fell Annex Farm, and certain securities amounting to $105,000.00 to Purdue University to be used for the benefit and service of the people of Lawrence County and southern Indiana. It should be noted that he not only gave the farm but that he provided ample funds to maintain it. He might have made this bequest for other worthy purposes. Only this morning it was announced that a wealthy lawyer has given $12,000,000 to the Law School of Michigan. Mr. Dunn was a lawyer and greatly interested in education and the legal profession but he had an undying love for the country, the hills, and the trees, the birds, fields, and farms, and above all the people of the country, so he gave this property to serve these interests. Could he have found a more worthy cause?

"Then there is another thing that I wish to point out. Moses Fell Dunn had a personal desire to demonstrate the possibilities of southern Indiana as a fruit growing section. He planted an orchard of 80 acres which he operated until he turned the property over to Purdue University in 1914. In his declining years he found that his undertaking had not been completed and it became a great disappointment to him, but he did not give up. After careful investigation he decided to turn the task which he had commenced and voluntarily undertaken over to Purdue University.

"Why did he do this? First, he wanted it to serve the people. Second, he wanted to be assured that it would become permanent and of greater value as the years go by. He must have recognized the underlying purpose of Purdue University—which is *service to the people of Indiana* and the nation. He must have had confidence in the officials of the institution. Other men of wealth might well follow his example.

The new gateway erected as a memorial to Moses F. Dunn and Antoinette Fell, commemorating the gift of the Moses Fell Annex Farm to the Purdue University Agricultural Experiment Station for the benefit of the agriculture of southern Indiana.

"In order to give permanent and lasting recognition and testimony in appreciation of his service to agriculture, country life and the people of Lawrence County and southern Indiana, and the state of Indiana, these gates have been erected by Purdue University in memory of Moses Fell Dunn and Antoinette Fell.

"We come this 12th day of June, 1930, to welcome you to Moses Fell Annex Farm and to rededicate the resources of his bequest to the cause of Agriculture and Country Life. May you appreciate, cherish, and honor the memory of Moses Fell Dunn by making the greatest possible use of this farm, its staff, and Purdue University, by applying the results of the work to your farms, and in the enrichment of your lives and by uplifting, serving agriculture, and those about you."

The occasion was honored by the presence of the Honorable Governor Harry G. Leslie who acted as principal speaker for the meeting.

GENERAL SOIL FERTILITY TEST

The soil fertility experiments carried on under the direction of A. T. Wiancko, Chief, and G. P. Walker, Associate, of the Agronomy Department are showing striking results that are of great value to the farmers of southern Indiana.

It will be noted, in comparing earlier reports and in examining the crops on the experiment field, that the spread between the good and poor treatments is becoming greater year by year, and that the better treatments are becoming more and more profitable. Without soil treatment, the average value of the crops per rotation of corn, soybeans, wheat, and clover is now $29.90 per acre. With lime, manure and phosphate, the value is $78.17, at an average cost of $8.05 for lime and phosphate.

The largest returns have been secured on the limed land, which has received an average of 6.8 tons of manure for corn and 450 pounds of fertilizer divided between the corn and wheat in the rotation of corn, soybeans, wheat and clover. (Plot 20.) The crop increases from this treatment have averaged $48.87 per acre per rotation as compared with the untreated land (plot 14), or a total of $171.04 in fourteen years. The cost of treatment outside of the manure, which was produced on the farm, has been $10.50 for three tons of ground limestone in 1917 and $4.44 every second year for fertilizer, or a total of $41.58 in the fourteen years.

Phosphorus is by far the most important plant food need of this soil. Applications of superphosphate have been highly profitable, either alone or in addition to manure. Without manure (plot 2) 225 pounds of 16 per cent superphosphate for corn and wheat in the four-year rotation has produced average crop increases of 16.2 bushels of corn, 6.2 bushels of soybeans, 6.8 bushels of wheat and 1,083 pounds of hay per acre, valued at $29.44 at a cost of $5.04 for the fertilizer. On land receiving an average of 6.8 tons of manure for corn, a similar use of superphosphate has further increased the crop yields by 9.5 bushels of corn, 5.2 bushels of soybeans, 6.2 bushels of wheat and 1,134 pounds of hay, worth $24.23 at a cost of $5.04 for the phosphate, showing that manure is not sufficient on this land. (Compare plots 16 and 18.)

Manure applied at an average rate of 5.7 tons per acre for the corn has produced average crop increases of 15.7 bushels of corn, 2.6 bushels of soybeans, 2.2 bushels of wheat and 263 pounds of mixed hay per acre, valued at $16.50, which amounts to an average return of $3.64 per ton of manure applied. (Compare plots 14 and 15.)

Ground limestone applied at the rate of three tons per acre in 1917 has so far produced average crop increases of 3.6 bushels of corn, 1.4 bushels of soybeans, 1.7 bushels of wheat, and 486 pounds of mixed hay per acre, valued at $28.14, up to the present time. (Compare plots 13 and 14.)

Lime and manure together have produced average increases of 19.3 bushels of corn, 4.0 bushels of soybeans, 3.9 bushels of wheat, and 486 pounds of mixed hay per acre, amounting to $22.13 for the rotation. (Compare plots 14 and 16.)

Applications of 300 pounds of 0-12-4 on corn and 300 pounds of 4-12-4 fertilizer on the wheat have produced average increases of 18.0 bushels of corn, 4.2 bushels of soybeans, 9.6 bushels of wheat, and 1,300 pounds of mixed hay per acre, amounting to $31.57 at a total cost of $8.88 for the fertilizer. (Compare plots 12 and 14.) The bulk of the increase, however, has been due to the phosphorus in the fertilizer, as is shown in the comparison of plots 2 and 8 with plots 3, 4, 6 and 7.

The field was laid out and tile drained in the spring of 1917. The original rotation was corn, wheat, clover and timothy, but this was changed in 1923 to corn, soybeans, wheat and clover, which is a more suitable rotation for this kind of land. All crops are removed except on plots 6, 7, 8, 10 and 11, where only the ear corn, wheat grain, soybean grain, and clover hay are removed, leaving all the roughage except the clover hay on the land in lieu of manure.

The treatments shown in the second column of the table are as follows: L=ground limestone; P=phosphorus; K=potash; N=nitrogen; Res.=crop residue; O=no treatment; M=manure.

All limed plots received 3 tons of ground limestone per acre in the spring of 1917. The fertilizer applications consist of 72 pounds of phosphoric acid, 24 pounds of potash and 12 pounds of nitrogen per acre per rotation. To the end of 1928 the phosphorus and potash were equally divided between the corn and wheat, but the nitrogen is all applied for wheat, half in the fall and half in the spring. Beginning with 1929 the wheat receives two-thirds of the phosphorus and potash and nitrogen as formerly, while the corn receives one-third of the phosphorus and potash in the row and also 4 pounds of nitrogen per acre on the plots receiving complete fertilizer.

The manure applications consisted of 6 tons per acre plowed under for corn in the first round of the rotation. Since then the rate of manuring has been equal to the amount of produce removed during the previous round of the rotation, except the wheat grain.

The following table shows the results of different soil treatments begun in 1917:

RESULTS OF GENERAL FERTILITY TEST

---

1. The crop rotation was changed in 1923 from corn, wheat, clover and timothy to corn, soybeans, wheat, clover.
2. Value of grain and hay increase due to residue alone.
3. Value of increase, cost and net for liming to date.
4. Value of increase due to manure used alone.
5. Value of increase per ton of manure.
6. Value of increase due to manure over lime.

NOTE.—In computing the financial results, corn has been valued at 60c, wheat at 80c and soybeans at $1.25 per bushel; stover and wheat straw at $2.50, soybean straw at $3.00 and hay at $10.00 per ton. Nitrogen has been charged at 20c, phosphoric acid at 7c and potash at 6c per pound. Ground limestone has been charged at $3.50 per ton.

Comparison of Different Phosphates

The object of this experiment is to determine the relative values of superphosphate, rock phosphate, bone meal, and basic slag as phosphatic fertilizers. Superphosphate and rock phosphate are also compared in several different proportions with and without lime, manure, nitrogen and potash fertilizers. The table following shows the results to date of treatments begun in 1916.

The largest returns have been secured from the combination of ground limestone, manure and medium to heavy applications of superphosphate (plots 5 and 26). The heavy treatment (plot 26) has produced average increases of 26.1 bushels of corn, 10.1 bushels of wheat, and 1,554 pounds of mixed hay per acre, valued at $34.20 per rotation or a total of about $170.00 per acre since 1916, when the treatments were begun, at a total cost of $39.20 for lime and phosphate. Fourteen dollars of this cost was charged for 4 tons of limestone, applied when the experiment was begun. (Compare plot 26 with 33.)

In combination with lime and manure, superphosphate has been the most profitable source of phosphorus, the returns per acre per rotation, above the cost of materials, from the lime and different phosphates averaging as follows: superphosphate, $17.48; basic slag, $16.83; steamed bone meal, $14.49; and rock phosphate, $12.01. (Compare plots 5, 3, 2 and 6.) In this comparison, superphosphate, basic slag and steamed bone meal have been applied at the rate of 48 pounds and rock phosphate at 192 pounds of phosphoric acid per acre with manure for each corn crop.

On limed land, superphosphate has been more efficient than rock phosphate in all cases, whether used in large or small amounts, and with or without manure or nitrogen and potash (compare plots 5, 11, 17, 23, 26 and 29 with plots 6, 12, 18, 24, 27 and 30).

On manured land without lime, rock phosphate and superphosphate have been about equally profitable (compare plots 11 and 12). However, it pays better on this land to use lime and superphosphate instead of rock phosphate (plot 5).

Without manure, rock phosphate alone has produced larger returns than the combination of lime and superphosphate although in both cases the crop yields have been too low to be profitable.

The lime, manure and superphosphate combination (plot 5) has produced larger returns over total cost than the manure and rock phosphate combination (plot 9) and is the more practical treatment for this land from the standpoint of both crop yields and profit.

This field was laid out and tile drained in the summer of 1915. The crop rotation is corn, wheat, and clover with all produce removed except second growth clover.

The treatments shown in the second column of the table are as follows: L=ground limestone; M=manure; St. B.=steamed bone meal; BS=basic slag; SP=superphosphate; RP=rock phosphate; N=12 pounds nitrogen; K=50 pounds potash.

Ground limestone was applied at the rate of 4 tons per acre in 1915.

Manure was applied at the rate of 6 tons per acre for corn in the first round of the rotation and since then in amounts equal to the produce removed except wheat grain. The phosphates are applied at the rates shown in the third column in the accompanying table.

RESULTS OF PHOSPHATE EXPERIMENT

AVERAGE YIELDS PER ACRE AND FINANCIAL STATEMENT PER ROTATION

(Plots 17, 18, 20 and 21 received 12 pounds of nitrogen and 50 pounds of potash per acre per rotation, all on the corn.)

1. Value of increase due to lime over manure.
2. Value of increase due to manure.
3. Value of increase per ton of manure.
4. Value of increase due to lime and manure.
5. Manured on Series B in 1916 and Series C in 1917.
6. Applied in 1916 and again in 1925.
7. Total value of increase, cost, and net returns to date at present prices.

NOTE.—In computing the financial results, corn has been valued at 60c and wheat at 80c per bushel; stover and wheat straw at $2.50, and hay at $10.00 per ton. Nitrogen has been charged at 20c, phosphoric acid at 7c and potash at 6c per pound. Rock phosphate (30%) has been charged at $15.00, and ground limestone at $3.50 per ton.

Variety Tests of Farm Crops

The selection of hardy, high-yielding varieties of the crops grown in any section is very important. To determine those best adapted for this part of the state, the most promising varieties of several crops have been compared each year for a number of years. Each variety has been harvested separately and the yields determined by weight. The land on which the variety tests are carried has been kept in a good state of fertility by uniform applications of fertilizer on wheat, and manure on each corn crop.

Pasture Experiments

The improvement of pasture land has a very definite place in the agricultural program for southern Indiana. Large areas of this section are better adapted to pasture purposes than to its present use. There is a considerable area of pasture land that is not producing in a satisfactory way. The development of better pastures will make possible the expansion of the live stock industry from both the beef cattle and the dairy cattle point of view.

Several years ago a series of pasture experiments was laid out in one of the uniform spots of the old pasture, and the results given in the accompanying table indicate the value of this work. Further work will be conducted to study the most economical methods of pasture improvement.

Various grass mixtures were used in connection with the different fertilizer treatments, so some very definite information is available for those who are interested in this important work. In connection with this, lespedeza has been seeded on poor unproductive spots, and is gradually extending over the pasture land. Lespedeza seems well adapted to our poor lands, on which more expensive methods of improvement are not practiced.

RESULTS OF PASTURE EXPERIMENT, 1924-1929

Plot No.	Treatment per Acre*	Green forage pounds per acre 1924	Green forage increase over untreated	1925	Cured pounds per acre average 1926-29	Cured forage increase over untreated

* Treatments applied at seeding time in April, 1923, and fertilizer repeated in fall of 1929. Plots 2 and 9 receive top dressings of 100 pounds of nitrate of soda per acre each spring.

All this experimental work, including some crop rotation experiments and the test of nitrogen top dressing of wheat will be seen on the fields.

HORTICULTURAL WORK

The Horticultural Department is carrying on a number of lines of work of interest to the fruit industry of the state. These projects are under the direction of Professor Laurenz Greene. Most of the experiments are being carried out by C. E. Baker, F. C. Gaylord, F. P. Cullinan, Monroe McCown and C. L. Burkholder. About 90 acres in all are planted in apple, peach, plum and pear.

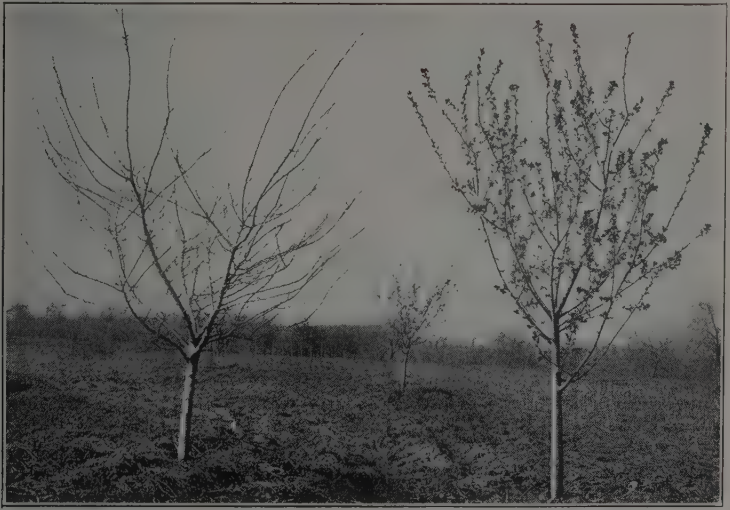
Most of the apple acreage was planted before the farm came under the management of Purdue.

Plum and Prune Variety Tests

In 1928 a three-acre block of some 15 promising varieties of plums and prunes were planted just north of the apple orchard. A few new varieties have been added since. The oldest trees in this block have had three summers' growth and a number of them had a nice bloom this spring and set some fruit. Plum and prune fruit buds are rarely injured by low winter temperatures but are as easily killed as peaches during bloom. One interesting observation in 1931 was made on the Roberts prune which was just beginning to show green leaf tips when the other varieties in the plot were in full bloom or already dropping their petals. (See picture of Robert's prune and Reine Claude plum.)

Peach Variety Tests

The Oriental Peach Moth invasion of this part of the country in recent years has had a decided effect on the matter of peach varieties. All varieties which ripen later than Elberta will be much more subject to attack and the later the ripening date the more serious the infestation. For this reason Salway and Krummel October have already been removed although they proved to be hardier in bud than Elberta. The Gold Drop and Crosby rows are still in the block but as the skin on these varieties is covered with



Roberts Prune on left and Reine Claude plum on right on April 22. Note delayed blooming period on Roberts Prune as compared to Reine Claude.

a thick fuzz they seem to be especially susceptible to Oriental Peach Moth injury for this reason as well as because they ripen later than Elberta.

J. H. Hale and Big Red were discarded several years ago as not being as desirable as Elberta. Greensboro has been hardy in bud but is a peach of very poor quality and most of the trees have been killed or seriously injured by low winter temperatures.

Rochester, an early yellow peach, and Champion, Belle of Georgia, and Hiley Belle (white fleshed varieties) are recommended for home orchards and local sales. All four varieties are superior to Elberta as a canning peach and the fruit buds are more resistant to low winter temperatures.

This test plot is South of the old Elberta peach orchards and rows are named on East end.

Old Peach Orchard

This block of trees is now in the 14th growing season. Last year's crop failure gave an opportunity to cut these old trees back severely. In spite of the very unfavorable growing conditions of 1930 they made a nice renewal growth and are carrying a good crop of fruit which required heavy thinning. In spite of this entire site being a very poor one for peaches this block of trees has produced five crops in the last ten years.

Pear Blight Plot

This is an area of about two acres of trees planted in 1930 West of the apple orchard in the alfalfa field. All trees are on

A peach tree in the Elberta block showing renewal growth following heavy heading back in spring of 1930.

Removing rough bark on apple trees as an aid in codling moth control.

roots resistant to blight and have Old Home bodies which also have been found to be blight resistant. The present plan is to bud in Bartlett and Wilder varieties 12 to 18 inches out on the scaffold branches this summer and to later start a regular spraying program in the pink and blooming periods to aid in controlling blight.

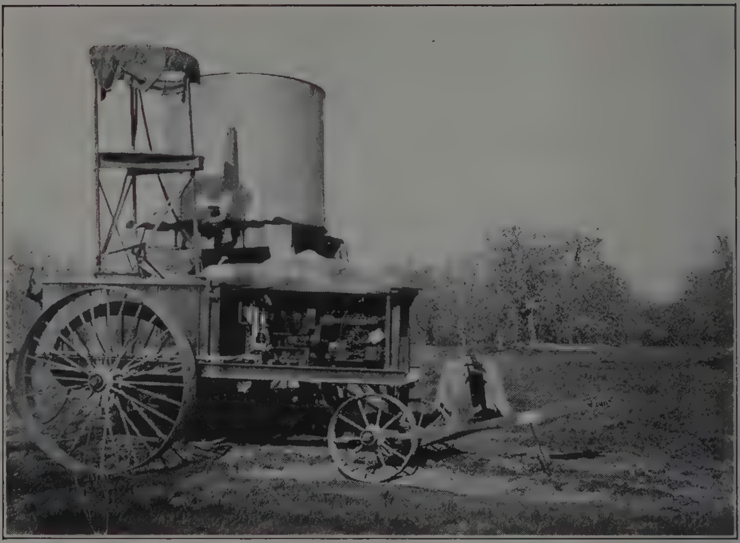
Apple Orchard

The control of codling moth has been a big problem in this orchard as well as in other commercial orchards in the Mitchell and Bedford areas. All of the apple trees have been scraped to remove loose bark and wintering over codling moth larva and a self-working codling moth band has been applied to each tree. The type of band used is one that has been developed by Mr. Marshall of the Purdue Entomology Department. The worms which crawl into these bands to pupate are killed, which does away with the work of examining each band and crushing the larva every ten days all summer. Growers who are having difficulty controlling codling moth should scrape their trees and give this new band a trial.

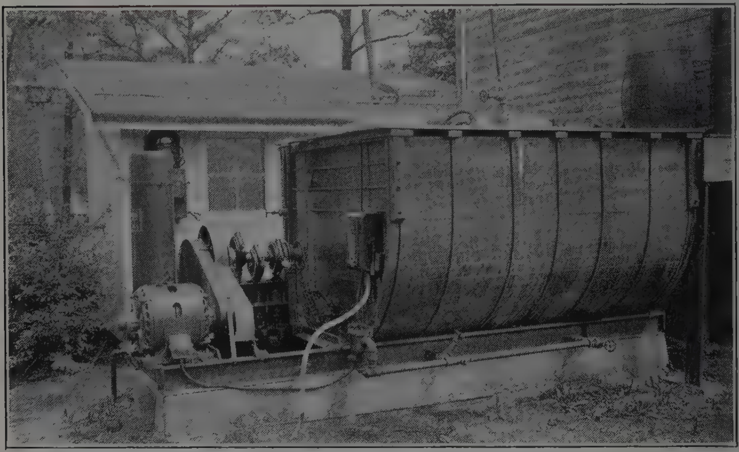
The packing shed has been made moth tight so that none of the hibernating worms inside the shed can get out into the orchard. This is a very important control measure.

Spray Residue

The continual reduction in U. S. arsenical tolerance on apples will soon make it necessary to revise the summer spray schedule or arrange to clean all fruit at harvest time. In 1930 a change was made in the July and August spray applications. Two oil-nico-



Portable sprayers with towers are used on half of the apple orchard to compare the cost and efficiency with the stationary sprayed block. The water tank is a substation fed by a half inch pipe from the main tank.



A view of the stationary spray plant. This outfit makes possible the prompt and efficient spraying of the orchard even if the ground is soft and muddy.

tine sprays were used in place of two of the arsenical sprays. This schedule failed to give satisfactory codling moth control under the unusual conditions of heavy second brood codling moth infestation and extremely dry weather of 1930. A late arsenical spray was used the latter part of August which made it necessary to clean all of the Jonathan and Grimes and most of the later ripening varieties in a weak hydrochloric acid solution. This practice was also followed in 1928 and the results of the two years' work along this line will soon be published in bulletin form.

Stationary vs. Portable Spraying

In the spring of 1929 all of the apple orchard north of the main water tower was piped for stationary spraying. This area was rough and difficult to spray with portable rigs. All of the work was done by farm labor at a cost of $32.35 per acre, laying all lines on the surface of the ground.

Reed and Son, Vincennes, Indiana, have just completed installing a stationary spray plant covering 200 acres at a cost of $39.21 per acre. In this case all pipe lines were buried from 18 to 36 inches deep.

Floyd Stout installed a stationary spray plant in the spring of 1930 on a ten acre block Southwest of Indianapolis. He hired $14.70 of labor and not allowing for his own labor the cost was about $80.00 an acre with all lines on surface. The same motor, pump and spray tank would of course care for a larger acreage which could be added to the present system at a cost of approximately $10.00 per acre.

The stationary block at the Moses Fell Orchard lost most of its crop by a late spring freeze and very few records were obtained in comparison with the 30 acre block to the South being handled by an up to date large capacity portable rig. It took 6½ hours to apply a spray on the stationary block to one side of the trees only. (There are 6 acres of unplanted area in this fifty acres.) Three gunmen were used in the orchard and an operator at the plant although the outfit has enough volume to carry four gunmen.

The plant went through the winter in good shape and the pink spray was applied to both sides of the trees in the stationary block in 1931 in 8½ hours using 3850 gallons of spray material. One grower near Indianapolis applied 3600 gallons of material in a 10-hour day using a large portable rig, tractor and two leads of hose. One of the most outstanding savings in labor and time of applications is on the portable block where a large outfit with a 250 gallon tank is being used in comparison with two years' records using a medium sized portable outfit and 200 gallon tank.

Bees

A small apiary has been established on the farm for the purpose of assisting in the pollination of bloom and helping to obtain a better set of apples. These colonies were started from small packages of bees containing a queen and several pounds of worker bees.

Apple Storage Investigations

During the past season the fifth year's study on the keeping of early varieties of apples in a farm storage has been completed. Fruit kept in a room of 1200 bushels capacity cooled by ventilation only has been compared with fruit kept in a similar room in which about 3.5 tons of ice has been used to cool the fruit. The ice was placed in a frame bunker with sheet iron drip pan beneath and an electric blower has been used to circulate the air within the room to maintain a uniform temperature.

A new shipment of "package bees" helped to increase the set of fruit in 1931.

These experiments have indicated that ice may be profitably used in southern Indiana to hold early fall apples in salable condition for short periods. In many seasons fruit that can be held in prime condition for three to six weeks can be sold for a much higher price than can be obtained immediately following harvest. Under these conditions the use of ice may lead to increased profits, as fruit held in uniced common storages frequently ripens so rapidly that its quality and value are greatly reduced after a few weeks.

The cost per bushel for the ice used has been gradually reduced over this five year period by shortening the icing period. This has been accomplished without corresponding loss in quality of the fruit. The costs per bushel for the five years are as follows: 1925-26, 23.5 cents; 1926-27, 26.9 cents; 1928-29, 18 cents; 1929-30, 14 cents and 1930-31, 13 cents.

Demonstration Farm Garden

Every Indiana farm should have a generous farm garden. To give a practical demonstration of the layout of such a garden an acre of the best land on Moses Fell farm has been set aside for gardening purposes. Only half will be used each year, the other half being planted to soybeans which will be plowed under in order to increase the fertility and organic matter in the soil.

The garden plot has been in Japanese clover continuously for the past seven years. Ten loads of stable manure were spread over the half acre to be cultivated in 1931 and 500 pounds of complete fertilizer were broadcast previous to planting.

The garden has been laid out as a practical demonstration of the makeup and layout of a garden that will provide an abundance of high quality fresh vegetables for summer and winter with ample supply for canning. Not only have the regular crops been planted but enough cantaloupes and watermelons have been included to provide the farm family with plenty of these delightful vegetables.

The garden will be operated for at least a five year period, records kept of cost of operation and quantities of vegetables of various kinds harvested. It is the hope that this demonstration garden will provide essential information as to the practical operation of a real farm garden. In addition, this garden will show the money value as well as the personal satisfaction that can be derived from a good garden on every southern Indiana farm.

See this garden located on the west end of the road leading west from the water tower.

It is important that the tops of the trees be properly sprayed if disease and insect control is effective. The use of the shade tree nozzle on the spray gun is shown here.

LIVESTOCK

The livestock work on the farm has been expanded during the last year to make it yield some valuable information to those interested in sheep and lamb production in southern Indiana. Eight head of purebred Shorthorn calves were imported from the Bingeman herd near Waterloo, Canada, to serve as a foundation for the herd which will be used to study several phases of breeding problems confronting cattlemen and to give specific information regarding the performance of dual purpose cattle. This project is being carried on in cooperation with the United States Department of Agriculture, Bureau of Animal Industry. In our livestock work we have had the benefit of the advice and cooperation of Professor F. G. King, Chief, and Professor Claude Harper, Assistant Chief, of the Department of Animal Husbandry.

The flock of Type C Merino ewes were culled and divided into two lots. One lot was bred to a purebred Merino ram and the other lot bred to a purebred Southdown buck. A lot of 25 western ewes and a lot of native ewes were also bred to Southdown bucks. Accurate records have been kept of the feed requirements for the

One of the heifer calves purchased to establish the Shorthorn herd which will be a part of an important co-operative project with the Bureau of Animal Industry, U. S. Department of Agriculture.

This calf is out of a Scotch Shorthorn cow with a good milk record. Individual records will be kept on each animal in the herd.

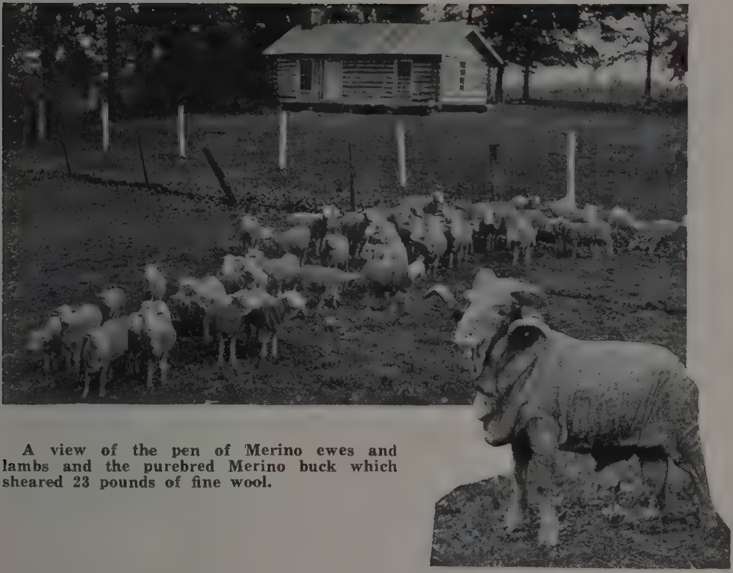
This calf was purchased to head the herd. It is now 20 months old and if it continues to develop satisfactorily, it should make a good sire.

ewes and the lambs so that costs, gains, profits and effect on wool production can be definitely determined. The lambs will be valued about June 10th and the data summarized for the meeting.

The western and native ewes have produced the largest number of lambs and these have gained faster than those from the Merino ewes. The Merino-Southdown lambs are larger and thriftier than the straight Merino lambs. This work will assist the sheepmen of southern Indiana to realize the greatest profit from their flocks.

The young cattle have made good growth since arriving at the farm January 5th. These animals range from 8 to 20 months of age and a few of them should calve next year. Milk and feed records will be kept on the cows and the dual qualities and performance of the calves will be measured as accurately as possible.

The top picture shows the group of Western ewes and their lambs.
Middle—The pen of native ewes and their lambs. These ewes were purchased locally for the test.
Bottom—Merino ewes and their lambs.
All lambs shown above were sired by purebred Southdown bucks.



A view of the pen of Merino ewes and lambs and the purebred Merino buck which sheared 23 pounds of fine wool.

The three purebred Southdown rams used in the sheep experiments.

POULTRY

A consistent effort is being made to develop one of the finest flocks of Barred Plymouth Rocks in the country. In this work Mr. S. M. Walford of the Department of Poultry Husbandry advises regarding the management and assists in the development of a constructive breeding program.

A uniform intermingling of the several Indiana and imported blood lines in the flock of 750 pullets and hens is beginning to show results in a more uniform, high egg production. The birds, entered in Indiana Record of Performance, are trapnested every day of the year, and an accurate record is thus kept of each bird's egg production and egg weight, as well as the body-weight of the bird.

A pen of high producing pullets that are making production records.

By pedigree breeding and wingbanding, the progeny of outstanding females is definitely identified. Lady Antoinette (B 7089), a 5-pound bird which laid 281 eggs averaging 23.5 ounces per dozen in her pullet year, was mated to a son of hers out of a Purdue male. Five daughters from this mother-son mating are now completing their pullet year in R. O. P. They came into production at an average age of 7 months, and their production to May 21st was 142, 144, 155, and 185, or an average of 156 eggs to date. They have been in production an average of 6¼ months, which makes the production per bird per month slightly over 25 eggs. Full brothers to these outstanding pullets sired the bulk of the chicks produced on the farm this spring.

Individual records are kept on each bird by means of trap nests. All of the chickens have leg bands and individual numbers.

Brooder houses are moved to a clean range each year to eliminate the possibility of disease.

TOBACCO EXPERIMENTS

The drought last year seriously affected the tobacco crop on the farm and the following table which gives the results clearly shows that the different fertilizer applications had little effect. This is particularly noticeable between the plots receiving 250 pounds and 500 pounds per acre. The trials were conducted on the same plots that were used last year because it was a piece of new ground with a good blue grass sod turned under.

Plot No.	FERTILIZER PER ACRE	Yield per Acre	Graded as follows:

OPERATING WATER PUMPS WITH ELECTRIC POWER

TRUMAN E. HIENTON
Department of Agricultural Engineering

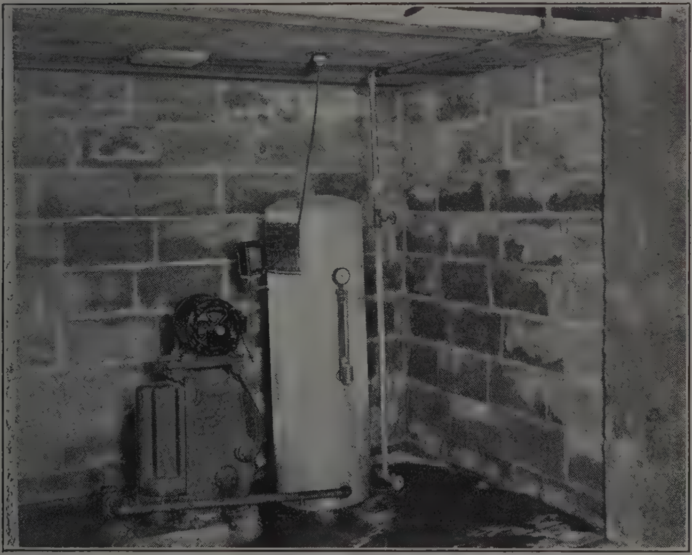

Fig. 1. Electric motor-driven deep-well pump in Tippecanoe County.

Deep-well pumps should be used where the lift from the level of the water in the well or cistern to the pump exceeds 22 feet. The pumping head must be located above the well although the pressure tank may be located at some other point. A convenient arrangement is shown where the well is drilled just outside of the basement wall and the pump is enclosed in a small room which joins directly to the cellar. The drop pipe may be pulled out of the well through the hole in the ceiling filled by the removable concrete block.

Electric energy is the most satisfactory source of power for operating the farm water pump. The daily demand for water on the farm requires a reliable power unit to operate the pump and the electric motor has been found to be the most dependable and economical for that purpose. The rapid extension of farm electric lines in the past eight years and the increase in the use of individual light plants has brought electric energy to nearly one-sixth of all Indiana farms. As a result, it is now possible for many farmers to utilize the electric motor to save time and expense in pumping water.

Electric Motor-Driven Pumps.—Water pumps are usually divided into two classes, shallow-well and deep-well. The first is recommended for use in pumping from wells or cisterns in which water is not more than 22 feet below the level of the pump. The deep-well pump is for use in pumping where the vertical lift from the water to the pump exceeds 22 feet.

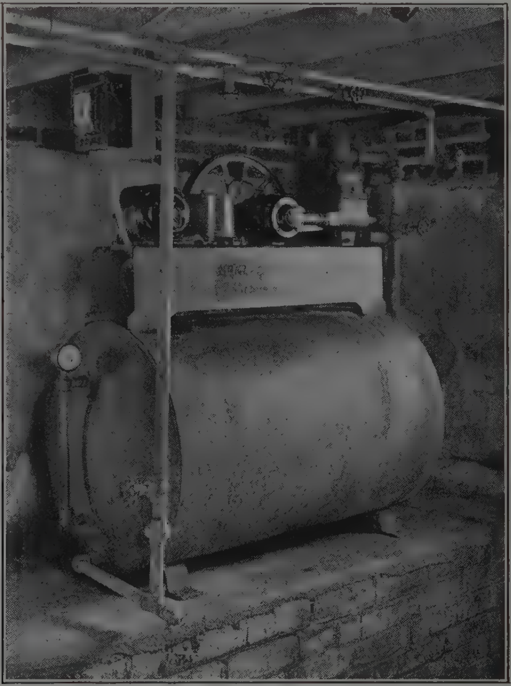

Fig. 2. Electric motor-driven shallow-well pump on a Clinton County farm.

Shallow-well pumps are recommended for use in pumping water which is not more than 22 feet below the pump. The pump may be placed above the well or cistern but is usually located with the pressure tank in the cellar of the house or in another building for protection from frost.

The shallow-well pump may be located above or at some convenient point near the well or cistern. This makes it possible to locate the pump in the basement of the house or other building to protect it from freezing. The pumping head of the deep-well pump must be located above the well although the pressure tank, where used, may be located away from the well.

A pump jack may be used with either shallow- or deep-well pumps but must be located over the well or cistern when used with a deep-well unit. Where a jack is used with a pump which forces water into a pressure tank, the tank is usually placed in the basement or other protected location.

The change from an engine to an electric motor for operating a pump seldom involves any material change in equipment. The drive pulley on the pump or pump jack must in most cases be exchanged for a larger one to obtain the proper speed of the pump. In situations where water is pumped into a pressure tank and automatic operation of the motor is desired, a switch, which controls the motor, must be installed. Belt drive which is most frequently used with engines is satisfactory for use with motors, but some type of belt tightener should be provided.

On many farms it is desired to install new pumping equipment when electric power becomes available. Typical complete pumping units for deep wells and shallow wells are shown, respectively, in Figures 1 and 2. Motor-driven pump jacks are also available as complete units, as shown in Figure 3. They may be secured with or without a pump but usually can operate any make of pump, designed for use with a pump jack. A pressure tank and automatic switch can also be secured for use with the pump jack.

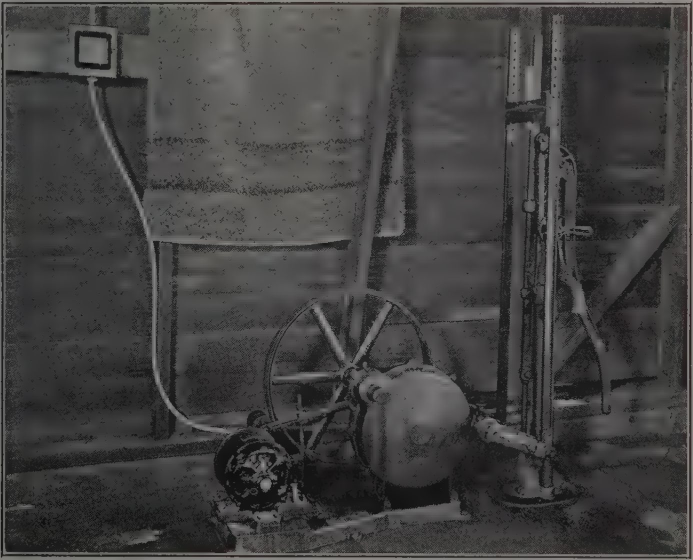

Fig. 3. Electric motor-driven pump jack on a Clinton County farm.

A pump jack may be used with either shallow- or deep-well pumps. It must be located above the well or cistern from which the water is pumped when used with a deep-well pump, but not necessarily so with a shallow-well unit. Automatic operation is possible, where water is pumped into a pressure tank, by the use of an automatic switch.

Wiring required for the installation of a motor on any pump should be installed by a competent electrician. Motors should be protected with fuses of proper size to prevent possible damage.

Energy Used for Pumping.—The amount of water pumped by a kilowatt-hour of electrical energy or a gallon of gasoline depends upon a number of factors. Several of the more important items which affect the amount of water pumped are the size and class of pump, depth of well, and pressure against which the water is pumped.

Tests were conducted on five makes of shallow-well plunger pumps in December, 1929, at the Purdue University Agricultural Engineering Department. The results of the tests on one pump, shown in Table I, are typical of those of all pumps tested in so far as energy consumption is affected by the lift and pressure. It will be noted that as the pressure, against which the water was pumped, increased, the energy consumed per 1000 gallons increased, and as the lift increased the energy also increased, while the capacity of the pump decreased with those increases in pressure and lift.

TABLE I.—ENERGY USED FOR PUMPING 1000 GALLONS OF WATER AT VARIOUS LIFTS AND PRESSURES.[1]

Lift feet	Pressure pounds	Capacity gal. per hour	Kw.-hr. per 1000 gal.
15	30	328.0	1.09
22	20	334.0	0.928
22	30	323.9	1.13
22	40	315.1	1.35

[1] Pump used was of double-acting, plunger type, rated to deliver 300 gallons per hour by the manufacturer.

The average consumption of the five shallow-well pumps with a 15-foot lift at 30 pounds gage pressure was 1.25 kilowatt-hours per 1000 gallons of water pumped. Similar results, secured on five farm-installed, shallow-well pumps where the water pumped was measured by meters, showed a consumption of 1.44 kilowatt-hours per 1000 gallons of water pumped, with pressures varying from 20 to 40 pounds. Energy required for pumping with deep-well pumps is greater than that with shallow-well pumps and increases with the increase in lift of the water.

Field survey records were obtained during 1930 in a study of cost of power for pumping water by P. F. Aylesworth of the Farm Management Department under the direction of the Agricultural Engineering Department. The average of eight records taken on shallow-well pumps driven by gasoline engines showed a consumption of 1.05 gallons of gasoline per 1000 gallons of water pumped against no pressure. Similar records taken on five shallow-well pumps driven by electric motors showed a use of 1.56 kilowatt-hours per 1000 gallons pumped against pressures of 20 to 40 pounds. With gasoline costing 12 cents per gallon and electric energy 5 cents per kilowatt-hour, the costs for pumping 1000 gallons of water under the above conditions were $0.078 for electric power and $0.126 for gasoline power. The results of the tests reported would indicate that under identical pumping conditions (both pumping against the same pressure) a greater difference in cost of power would result.

Another item not included in the foregoing cost of power, which is difficult to evaluate, is that of labor involved in starting the engine. Electric motors, where equipped with automatic switches, require no attention for starting or stopping them.

Extension Bulletin No. 170, "Water Systems for the Farm Home," of the Purdue University Agricultural Extension Department describes pumps operated by all types of power and will be of interest to those who do not have electric power available.

*Indiana Crops and Livestock, 1931. Department of Agricultural Statistics.

SEVENTEENTH ANNUAL REPORT OF THE CREAMERY LICENSE DIVISION

T. H. BINNEY

In 1927 the Creamery License Division of Purdue University Agricultural Experiment Station entered into an agreement with the United States Department of Agriculture to collect production figures from the dairy manufacturing plants in Indiana. Each quarter, blanks are sent out from the Bureau of Agricultural Economics' office in Washington to all dairy plants in the state and returned to them through the Creamery License Division. A carbon copy of all figures are filed in the office of the Creamery License Division and the original copy is sent to Washington. In addition to these figures production reports are received from all licensed dairy plants in the state at the time they apply for creamery licenses. With the information received, it is possible to compile reliable statistics concerning the total production of licensed manufacturing plants.

The following table is a summary of the reports received from licensed plants for the years indicated:

OUTPUT OF LICENSED PLANTS IN INDIANA FOR 1916, 1920, 1924, 1929 AND 1930

	1916	1920	1924	1929	1930
Pounds of Butter	33,026,796	42,577,180	53,462,104	62,700,705	63,248,581
Pounds of Milk	55,059,940	155,950,136	257,417,090	537,463,634	613,005,756
Pounds of Cream	5,799,663	12,224,488	25,219,252	36,052,145	29,892,859
Gallons of Ice Cream	2,111,701	4,132,318	4,865,465	5,250,345	4,664,131
Pounds of Cheese	82,667	233,806	574,686	10,126,417	11,956,315
Pounds of Sweetened Condensed Milk	1,619,880	6,920,592	8,735,498	3,355,734	2,557,973
Pounds of Evaporated Milk	13,657,248	10,265,791	23,912,054	37,973,360	50,602,364
Pounds of Bulk Evaporated Milk	2,774,880	5,977,716	19,065,245	31,102,559	43,054,573

By comparing the figures for 1930 with those for 1929 in the above table, it will be noted that most of the manufactured products show an increase. The increase in the amount of butter made is 547,876 pounds, or slightly less than 1.0 per cent. A total of 613,005,756 pounds of milk and 29,892,859 pounds of sweet cream were sold in licensed plants during the past year. This represents an increase of 14.0 per cent of milk and a decrease of 20.6 per cent of cream in 1930 as compared with 1929. The amount of ice cream manufactured during the past year shows a decrease of 586,214 gallons or 12.5 per cent. Cheese production increased 1,829,898 pounds or 18.0 per cent. Sweetened condensed milk decreased 797,761 pounds or 31.1 per cent, evaporated milk (case goods) increased 12,629,004 pounds or 33.2 per cent, and bulk evaporated milk increased 11,952,014 pounds or 38.4 per cent.

In addition to the above products dairy plants of the state manufactured 16,298,695 pounds of condensed skim milk; 2,333,165 pounds of evaporated skim milk; 4,612,506 pounds of concentrated skim milk (for animal feed); 8,099,871 pounds of condensed or evaporated buttermilk; 1,690,196 pounds of dried or powdered skim milk; 2,147,463 pounds of dried or powdered buttermilk, and 153,150 pounds of malted milk.

An estimate of the total amount of dairy products manufactured in the state may be secured by using the above statistics and estimating the amount of dairy products manufactured and sold in the plants which are not licensed. A large number of ice cream plants and market milk plants buy milk on a gallon or weight basis rather than on a butterfat basis and do not come under the jurisdiction of the Creamery License Division.

Amount of Butter, Milk, Ice Cream, Condensed Milk and Cheese Estimated as Produced in Indiana During 1930

Pounds of Creamery Butter	63,248,581
Pounds of Dairy Butter	10,297,908
Pounds of Milk Consumed	1,605,559,991
Gallons of Ice Cream	9,691,509
Pounds of Condensed and Evaporated Milk	96,214,910
Pounds of Cheese	11,956,315
Pounds of Cottage Cheese	3,202,849

By taking the amount of milk used in the manufacture of each of the various dairy products the total milk production of the state may be calculated. In making this calculation, it has been necessary to estimate the amount of milk and cream consumed direct, the amount of dairy butter made, the amount of milk fed to calves, and the amount of milk lost on farms and in factories.

Total (Estimated) Milk Production

Creamery butter used	1,328,220,201	pounds
Dairy butter used	216,256,068	pounds
Milk consumed direct	1,605,559,991	pounds
Ice cream used	133,258,248	pounds
Cheese used	119,563,150	pounds
Condensed milk used	240,537,275	pounds
Milk fed to calves	105,774,000	pounds
Milk shipped out of state	266,231,898	pounds
Losses on farms and in factories	120,462,025	pounds
Total	4,135,862,856	pounds
Milk shipped in	211,457,653	pounds
Total milk production in Indiana	3,924,405,203	pounds

Creamery Licenses

In order to comply with Section 6 of the Creamery and Testers' License Law (Acts of 1913, Chapter 340), every creamery, shipping station, milk factory, cheese factory, person or agent, firm, company, association or corporation, receiving, buying and paying for milk or cream on a butterfat basis, is required to hold a creamery license. Unless revoked for a violation of the Law or Rules and Regulations under which it is granted, a creamery license is valid for a year.

During the past year 1893 creamery licenses were issued as compared with 1932 for the previous year. Station licenses show a decrease of 64 in number while the number of plant licenses show a gain of 25 in number.

The following table is a summary of the number and kinds of plants issued creamery licenses during the year ending March 31, 1931, and for previous years as indicated.

CREAMERY LICENSES ISSUED FROM 1924 TO 1930 INCLUSIVE

PLANTS AND STATIONS	Number and Year						
	1924	1925	1926	1927	1928	1929	1930
Butter	51	51	64	58	56	58	56
Milk	71	78	91	108	129	141	162
Ice Cream	15	14	17	15	11	16	18
Cheese	4	3	3	9	18	17	18
Condensed Milk	7	4	7	8	8	9	8
Butter and Milk	34	31	33	43	39	33	36
Butter and Ice Cream	17	16	12	14	17	13	10
Butter and Condensed Milk	1	1	1	1	0	0	0
Butter and Cheese	0	0	0	0	3	2	1
Butter, Milk, and Ice Cream	12	16	13	16	13	15	20
Butter, Milk and Condensed Milk	2	4	4	4	5	5	7
Butter, Milk, Ice Cream and Condensed Milk	6	6	4	6	7	7	6
Butter, Milk, Cheese and Condensed Milk	0	0	0	0	0	1	0
Milk and Ice Cream	10	13	19	20	24	18	19
Milk and Condensed Milk	2	4	3	3	2	5	4
Milk, Ice Cream and Condensed Milk	2	2	1	2	2	3	2
Milk, Ice Cream and Cheese	0	0	0	0	0	1	1
Total number of Plants	234	243	272	307	334	344	369
Stations	1,588	1,618	1,631	1,653	1,614	1,588	1,524
Total Licenses Issued	1,822	1,961	1,903	1,960	1,948	1,932	1,893

With the exception of plants handling whole milk, the number of plants handling the various dairy products have remained fairly constant for the past three years. Milk plants show a gain of 21 in number over the previous year.

The following table shows the number of plants which reported each of the five major products handled in licensed plants for the years indicated:

PRODUCT	Number of Plants Reporting						
	1924	1925	1926	1927	1928	1929	1930
Butter	123	125	131	142	140	134	136
Milk	139	154	168	202	221	229	257
Ice Cream	62	67	66	73	74	73	76
Cheese	4	3	3	9	21	21	20
Condensed Milk	20	21	20	24	24	30	28

The accompanying map shows the distribution of plants and stations in the state. The larger circle containing a number is the number of licensed plants operating in each town, while each small circle represents a cream station.

Testers' Licenses and Examinations

All dairy plants or stations, or person, or agent buying milk or cream on a butterfat basis must have in their employ a licensed tester who shall supervise and be responsible for the operation of the Babcock test of milk and cream.

Before licenses are issued testers must pass an examination, which consists of both laboratory and written work. The laboratory work consists of testing duplicate samples of both milk and cream. The written work consists of answering twenty questions taken from a list of questions furnished all testers before the examination. (Circular 41.)

Twenty-three hundred and ninety-five testers' licenses were issued during the past year; a decrease of one hundred and sixty-seven from the previous year's total of twenty-five hundred and sixty-two.

March-1931

Location of Licensed Plants and Stations for Year Ending March 31, 1931.

NUMBER OF CANDIDATES EXAMINED AND TESTERS' LICENSES ISSUED FOR THE YEARS ENDING MARCH 31, 1920, 1924, 1928, 1930 AND 1931.

	1920	1924	1928	1930	1931
Number of Individual Examinations	1,339	850	904	691	518
Number of Failures	226	125	290	144	79
Number of Persons Passing Examination	1,113	725	614	547	439
Number of Testers' Licenses Issued	2,371	2,518	2,661	2,562	2,395

The results of the seventy examinations which were held at the nine examination points in the state are given in the following table:

RESULTS OF TESTERS' EXAMINATIONS 1930-1931

PLACE OF EXAMINATION	Number of Examinations	Number of Candidates	Average Grades (Per Cent)		
			All Candidates	Candidates Passed	Candidates Failed
Lafayette	12	108	80.7	85.1	42.1
Muncie	8	54	79.0	84.5	42.1
Fort Wayne	10	81	83.2	87.0	56.6
Plymouth	1	8	84.4	84.4	....
New Albany	6	22	76.8	81.0	50.3
Evansville	8	56	75.8	82.0	58.9
Terre Haute	8	57	77.3	81.4	60.3
Indianapolis	8	62	79.1	80.3	59.0
North Vernon	9	70	80.7	82.6	69.7
Totals	70	518	Aver. 79.7	84.0	56.0

Glassware Inspection

With the exception of cream pipettes, all Babcock testing glassware used in the state must be inspected for accuracy by the Purdue University Agricultural Experiment Station before it may be used in Indiana dairy plants and cream stations. Only test bottles and pipettes conforming to specifications set forth in the Creamery and Testers' License Law (see Circular 41) are examined for accuracy. All pieces of glassware found to be correct are stamped with the letters "S. G. P.," meaning Standard Glassware Purdue.

Nine-gram weights used in weighing cream are also tested and are stamped "S. G. P." if within the tolerance allowed.

During the past fiscal year 34,940 pieces of Babcock testing glassware were examined by the Glassware Inspector of the Agricultural Experiment Station. In addition 204 nine-gram weights were inspected and all found to be correct. This is 19,672 pieces of glassware and 290 nine-gram weights less than were inspected last year.

The number of pieces of glassware inspected during the past year is less than for any year since 1916 and 17,724 pieces below the average per year since the Creamery and Testers' License Law became effective. The percentage of incorrect glassware is the highest since 1921.

The following table gives the amount of each kind of glassware inspected, and the number of pieces found to be incorrect:

GLASSWARE INSPECTION

KINDS OF GLASSWARE	Total Number of Pieces	Number Incorrect	Per Cent Incorrect
Cream test bottles	20,634	116	.562
Milk test bottles	12,288	2	.162
Milk pipettes	2,018	0	.000
Summary	34,940	118	.337

Licenses Revoked

Licensed milk and cream testers who do not test in accordance with the provisions of the Creamery and Testers' License Law and the Rules and Regulations under which licenses are granted may have their licenses revoked. Such action is taken by the Purdue University Agricultural Experiment Station upon recommendation of the Examining Board. Before recommending the revocation of a license, the tester appears before the Board where the evidence of incorrect testing is presented. After hearing the evidence presented by the Creamery License Division, and the statements of the tester, the Board recommends what action should be taken.

The following testers' licenses were revoked during the past year:

Mr. Cecil Goldsberry, Rensselaer, Jasper County, Indiana; tester for Rensselaer Creamery and Produce Company, Rensselaer, Indiana.

Mr. Thomas Patterson, Loogootee, Martin County, Indiana; tester for Evansville Packing Company, Evansville, Indiana.

Mrs. Oma Ohmart, North Manchester, Wabash County, Indiana; tester for Cloverleaf Creameries, Huntington, Indiana.

Mrs. Carrie Amburn, Winchester, Randolph County, Indiana; tester for Sherman, White & Company, Fort Wayne, Indiana.

Mr. V. N. Jones, Attica, Fountain County, Indiana; tester for Beatrice Creamery Co., Chicago, Illinois.

Mr. L. A. Blackburn, Oakland City, Gibson County, Indiana; tester for the Indiana Produce Company, Huntingburg, Indiana.

Mr. J. L. Glover, Covington, Fountain County, Indiana; tester for Sugar Creek Creamery Company, Danville, Illinois.

Miss Achsa Heaney, Bainbridge, Putnam County, Indiana; tester for Sugar Creek Cramery Company, Danville, Illinois.

Mrs. Bertha Dorton, Matthews, Grant County, Indiana; tester for Swift & Company, Marion, Indiana.

UNIVERSITY OF [illegible] LIBRARY

Circular No. 186 1931

MAR 11 1932
LIBRARY

INSPECTION OF AGRICULTURAL SEEDS

Fine Growth of Red Clover Resulting from Planting of Clean Seed.

Agricultural Experiment Station
Purdue University
Lafayette, Indiana

This circular contains a report of the Agricultural Seed Inspection for the year ending June 30, 1931. The complete analysis of 1,122 official seed samples is given with full particulars. In addition 2,553 free test samples of seed were tested during the year.

In accordance with a ruling of the State Seed Commissioner, wholesale seedsmen are required to attach at least one state label to each package of seed delivered to the retail seedsman, who, in turn, is required to attach sufficient additional labels to cover the weight of the package.

Since it is impossible to test all seed promptly during the rush season, directions are given for making germination tests at home.

Shipments of seed seriously misbranded were withdrawn from sale until dealers relabeled such seed correctly and made adequate refunds.

Proper use of this publication will enable purchasers to discriminate between seedsmen who handle good seed and those who handle poor seed. Before buying seed farmers are urged to examine Table VI, "The Standing of Seed Distributors," and Table VII, "The Results of Tests on 1,122 Official Samples."

INSPECTION OF AGRICULTURAL SEEDS

H. R. KRAYBILL, State Seed Commissioner

O. S. ROBERTS R. O. BITLER REGINA B. SCHULTE*
EDITH M. PATT PAULINE BALBACH

This circular contains the results of the inspection of agricultural seeds for the period from July 1, 1930, to June 30, 1931. The inspectors visited the seed dealers in all sections of the state and collected 1,568 official samples of seed. Complete analyses of these samples were made and reports were sent to the retail dealers as well as to the distributors of the seed. In addition 2,553 free test samples, 834 packets of garden seeds, and 38 Custom House samples were analyzed. The testing of these samples entailed the making of 3,201 purity tests, 18,528 germination tests, 25 examinations, and 114 identifications.

The Indiana Seed Law is essentially a correct labeling law. The law does not prevent the sale of poor seed. It merely requires that definite information be placed on the label in order that the purchaser may decide for himself whether he wishes to use good seed or poor seed. In order that the necessary information may be available the law requires that the seed be labeled with official Indiana State Labels showing the minimum percentage of purity and germination and the maximum number of each of the noxious weed seeds per pound. The purpose of the law is to give the purchaser sufficient information to enable him to buy good seed and also to protect the honest and reliable seed dealer and farmer from the practices of the unscrupulous, dishonest, and careless seedsman.

RESPONSIBILITIES OF THE WHOLESALE SEEDSMAN

The wholesale seedsman is required to attach at least one Indiana State Label to each package of seed delivered to the retail seedsman.

RESPONSIBILITIES OF THE RETAIL SEEDSMAN

The retail seedsman is required to attach sufficient state labels properly filled out to each package of seed to cover the total weight of the seed before the seed is offered or exposed for sale. These labels can be chosen of such denominations of weight so that they may be removed and attached to a portion of the seed which may be sold from the original package.

---

* In cooperation with the Seed Laboratory, Bureau Plant Industry, U. S. D. A.

It should be remembered that every package of seed of one pound or more when sold for seeding purposes must have attached to it sufficient state labels properly filled out to cover the total weight of the package. It should also be remembered that it is just as much a violation of the state law to offer or expose seed for sale for seeding purposes without tagging to full weight as it is to sell the same without tagging.

RESPONSIBILITIES OF THE PURCHASER

The purchaser should examine the official label carefully before purchasing seed and ascertain whether the seed is of the quality he desires. He should insist that all seed which he purchases be tagged properly with official state labels. Attention should be paid to the date of germination on the seed tag. If the germination test was made more than six months before, in many cases it will be well to insist upon a more recent germination test. Table VI gives the standing of the distributors as determined by the 1931 inspection and Table VII shows the results of the analyses of 1,122 official samples. A study of these tables will enable you to determine the quality of seed handled by the various seedsmen and whether the seed which they sold met their guarantee. The seed law is designed to offer you protection but it will not give you that protection unless you make use of the opportunity which the law provides for you.

FARMERS' EXEMPTION

A farmer is exempt from the provisions of the seed law when the seed is grown, sold, and delivered by that farmer on his own premises to the purchaser himself. If, however, the seed is advertised for sale by the public press, circular or catalogue, or if the seed is delivered by a common carrier, the farmer is considered as a vendor and must comply with the provisions of the act. Seed taken to community sales for sale must be labeled in accordance with the law.

FREE TESTING OF SEEDS

During the past year 2,553 samples of seed were tested free of charge for farmers and seedsmen. The privilege of having these tests made is one of much value to the farmer and the smaller seed dealers who do not have facilities for testing seeds. Not all of the tests requested can be made promptly during the busy season from January to March. For that reason it is important that you send your samples in as early as possible, preferably from September to December.

Satisfactory tests may be made of the larger field seeds at home, leaving the laboratory facilities of the Experiment Station available for the grasses and clovers which are more difficult to analyze.

DIRECTIONS FOR MAKING YOUR OWN GERMINATION TESTS

The seed to be germinated should be mixed thoroughly and the required number of seeds (100 seeds of grains and 200 of clovers and other small seeds) counted out just as they come.

The plate germinator is satisfactory and very simple to operate. Place the seeds to be germinated between two thicknesses of folded blotting paper or cloth (heavy grade of muslin or canton flannel). This should be moistened and placed between ordinary tin or porcelain plates and kept in a warm room where the range in temperature is from approximately 85 degrees during the day to 65 degrees at night. Select a place for the test not too near a window, stove or register.

The time required for germination tests differs with different kinds of seed. Under favorable conditions grass and clover seeds begin to sprout in three or four days. Continue your tests ten days or two weeks.

Examine your tests every two days, making a record of the number of seeds that have sprouted. Also keep the blotting paper or cloth sufficiently moist. The number of seeds which germinate out of the 100 seeds will give the percentage of germination.

DIRECTIONS FOR TAKING OF SAMPLES

1. The minimum weight of seed forwarded for test should be approximately:
   (a) Two ounces (cupful) of grass seed of any kind or of white and alsike clover;
   (b) Five ounces (cupful) of red and crimson clover, alfalfa, millet, flax or seed of like size;
   (c) One pound (pint) of cereals or seed of like size.
2. They may be drawn:
   (a) With seed triers;
   (b) With long stickers;
   (c) By hand, taking approximately equal parts of the sample from at least three different places in the sack, including the top and opposite sides as near the bottom as practicable.
3. Samples should be drawn from each bag when there are not more than five bags in the lot, from every fifth bag when there are more than five bags, but never from less than five bags. Each sample so drawn is combined into one composite sample.

TOLERANCE

Under the most perfect and approved conditions of testing seeds variations will occur in purity and germination tests. For this reason the Association of Official Seed Analysts has adopted tolerances or allowances for purity and germination tests. Samples of seed with a guarantee within the tolerances are not considered to be seriously misbranded under the provisions of the Indiana Seed Law, but seed dealers will be expected to change the guarantee on the unsold portions to correspond to the analysis found by the Seed Commissioner.

TABLES OF TOLERANCES FOR GERMINATION TESTS

Percentage of Germination	Percentage of Allowable Variation
90 or over	6
80 or over and less than 90	7
70 or over and less than 80	8
60 or over and less than 70	9
50 or over and less than 60	10
40 or over and less than 50	10
30 or over and less than 40	9
20 or over and less than 30	8
10 or over and less than 20	7
0 or over and less than 10	6

TOLERANCE FOR PURITY TEST

In determining the tolerance for purity the sample shall be considered as being made up of two parts: (1) pure seed and (2) everything not pure seed. The tolerance allowed shall be two-tenths of 1 per cent plus 20 per cent of the lesser part. Example: Seed marked 98 per cent pure, the lesser part is 100 minus 98, or 2. Twenty per cent of 2 equals 0.4. Therefore, the tolerance allowed would be 0.2 plus 0.4, or 0.6.

VIOLATION OF THE LAW

It is a violation of the State Seed Law to offer, expose for sale or sell seed without having it tagged to full weight with official labels or to misbrand the seed. During the past year eight cases of non-tagging of seed and seven cases of misbranding were called to the attention of prosecuting attorneys. The cases resulted in thirteen convictions and two not reported by prosecuting attorney to date.

REFUNDS

Several cases of misbranding have been settled by the seedsman replacing the misbranded seed with new lots of seed or by refunding to the purchaser the cost of the seed. The payment of refunds and the exchange of the seed does not cancel the violation, but it does show the seedsman's good intentions and indicates that he is willing to do all that he can to correct the violation. During this year refunds amounting to $68.25 were paid by seedsmen to the consumer.

FILLING OUT OFFICIAL LABEL

Purity

The minimum purity means the percentage of pure seed of the kind and variety given on the official label. Statements of purity, as 97 per cent, including 2 per cent crop seeds, or 95 per cent and 2 per cent crop seeds, will not be permitted. In cases where the seed contains two or more kinds of agricultural seed, each present in excess of 5 per cent, the seed should be labeled with the green colored mixture labels, Style C.

The percentage of purity on the large seeds such as soybeans, corn, wheat, vegetable seeds, etc., must be given on the official label the same as on any other seed.

The filling out of the column "per cent of seed" on the mixture labels can be best explained by an example. For instance, if a mixture is composed of 60 per cent Kentucky Blue Grass with a purity of 80 per cent and 40 per cent of Red Top with a purity of 90 per cent, the per cent of Blue Grass should be given as 48 per cent, obtained by taking 80 per cent of 60. The Red Top should be given as 36 per cent, obtained by taking 90 per cent of 40.

Germination

There still appears to be some misunderstanding as to the method of stating the percentage of germination on the official label. The term minimum germination means the percentage of sprouts obtained in the prescribed time for the test. If the seed contains hard seeds this percentage should be stated after the term "hard seed" on the official label. In no case should the sum of the percentage of sprouts and hard seeds be given as percentage of minimum germination.

Distributors should not ship seed until the germination test is completed. The statement "In Test" on the official label does not meet the provisions of the seed law. Further, if there is a demand for the seed the dealer may be tempted to sell the seed before he receives a report on the germination, thus placing himself liable to prosecution.

Noxious Weed Seeds

The number per pound of each of the noxious weed seeds present must be listed on the reverse side of the tag irrespective of the number present. The term "trace" is not permissible. The statement of the noxious weeds in terms of per cent or in terms of proportion will not be permitted.

Place Where Grown

The official tag must give the name of the state, territory or foreign country where the seed was grown. Terms such as Domestic, U. S. A., Northwestern, and Central States do not meet the requirements of the law, and seed found so labeled will be immediately removed from sale until the tags have been corrected.

Certified, Verified and Affidavit Seed

Certified seed is seed whose purity, germination, and variety is certified to by some state certifying agency or an agency closely associated with some state office or department. The seed is shipped in sealed sacks with a certified seed tag attached. During the growing season the fields are inspected to ascertain trueness to variety of crop, and after the harvest the seed is tested to determine whether it meets the prescribed standards of the certifying agency. In Indiana the Indiana Corn Growers' Association certifies corn, wheat, and soybeans. The other most commonly certified seed found in the state is Grimm Alfalfa.

Verified-Origin seed is seed whose origin is attested to by certain government approved seed dealers. Seed verification service deals with origin only, meaning Place Where Grown, and gives no guarantee as to the variety, purity or viability of the seed. At the present time red clover and alfalfa are the only seeds verified as to origin. Verified seed is tagged with tags bearing the official verification emblem.

Affidavit Grimm is alfalfa seed for which the grower has made affidavit as to its being Grimm Alfalfa. This affidavit seed is not regulated by either State or Federal Government.

Bargain Seed

A considerable quantity of unclean, weedy, so-called pasture mixtures of low viability has been shipped into the state by certain mail order seedhouses. By means of extensive advertising in leading farm papers many unsuspecting buyers have been influenced in purchasing these dangerous and, in many cases, worthless lots of seed. These mixtures appear to consist of screenings, tailings, and low grade seed mixed together in order to disguise their real quality. The low price attracts the buyers who forget that good seed is not sold below the prevailing market price and that good seed is the cheapest in the end. Most of these cheap seeds lead to poor stands and infestation of the soil with many troublesome weeds.

Summary of 1931 Inspection

Most of the official samples examined during 1931 met their guarantee very closely and were equal in this respect to those of 1930, the best year of compliance since the passage of the seed law. However an examination of Table III shows clearly that the quality of much of the seed could be improved by more thorough cleaning.

With the exception of a few the seedsmen are showing an increased interest and desire to cooperate with the department in the enforcement of the seed law.

Tables IV and V show the percentage of official samples of red clover, alfalfa, sweet clover, alsike clover, and timothy having various noxious weed seeds. The most noticeable fact is that 28.79 per cent of red clover samples and 20.83 per cent of the alfalfa samples contained dodder seed. Compared with 1930, the red clover samples showed a slight decrease and the alfalfa samples a 50 per cent decrease in the presence of dodder seed. However there are too large a percentage of samples showing the presence of dodder seed when one considers that dodder is one of the worst noxious weeds in Indiana.

TABLE I.—AVERAGE ANALYSIS OF SAMPLES IN 1922 SEED INSPECTION

	Number of Samples	Purity per cent	Inert Matter per cent	Germ. per cent	Hard Seeds per cent	Number Weed Seeds per Pound	No. Noxious Weed Seeds per Pound

ELECTRIC BROODERS ON INDIANA FARMS

Truman E. Hienton
Department of Agricultural Engineering

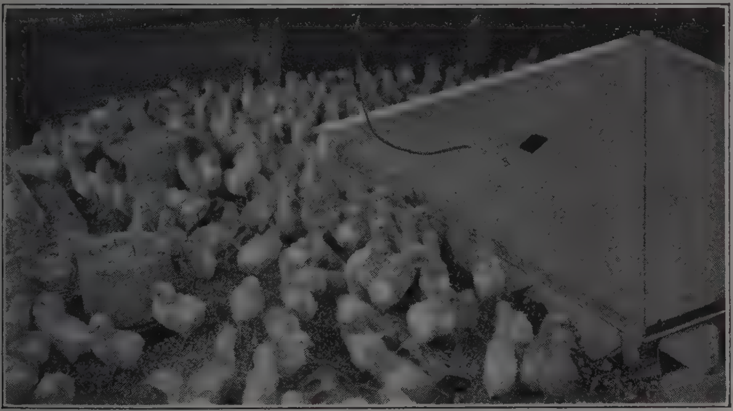

Fig. 1. Electric Brooder in Operation on Howard County Farm.

Electric brooders are being used in increasing numbers on Indiana farms where electric service is available from central station plants. This 660-watt electric brooder is shown during its second year of operation on a farm in Howard County.

Many millions of chicks are raised each year in Indiana by brooders heated by various devices. Electrically heated brooders are probably the newest and least known but are receiving greater attention and increasing in use as electric lines are extended to farms throughout the state. This increase in use of electric brooders has facilitated the securing of data regarding two of their important operating characteristics, current consumption and mortality of chicks.

During the past three years 48 electric brooders in operation on Indiana farms have been metered under the direction of the Department of Agricultural Engineering to determine their use of electrical energy. Records were kept by their operators on the chicks lost, energy used, and duration of brooding periods. The averages of the results obtained each year are given in Table I and the ranges in results are shown in Tables II and III.

TABLE I.—AVERAGES OF RESULTS FOR 48 ELECTRIC BROODERS OPERATED ON INDIANA FARMS IN 1929, 1930, AND 1931

Year	1929	1930	1931	All
Number flocks	6	28	14	48
Average number chicks started per flock	447	362	362	372
Average mortality, per cent	9.5	12.3	16.0	12.9
Average number chicks raised per flock	404	317	304	324
Average kilowatt-hours per chick raised	0.419	0.359	0.678	0.456
Average cost for fuel per chick raised, cents*	1.26	1.08	2.03	1.31
Average brooding period, days	49	40.5	50	41.4

* Electric energy at 3 cents per kilowatt-hour.

Mortality of Chicks

Percentage of chicks raised by any brooder is dependent upon a number of factors so that mortality may or may not be a true indication of the performance of the brooder. Disease conditions may be present and result in losses which are not chargeable to the brooder. Usually, however, the success of a brooder is measured in the percentage of chicks raised, so that these figures were secured for the electric brooders which were metered.

It is estimated by Prof. C. W. Carrick in Purdue University Agricultural Extension Bulletin 177 that more than a third of the chicks started on Indiana farms die before they reach marketable age or maturity. The average mortality of chicks, during the brooding period, started under 6 electric brooders in 1929 was 9.5 per cent, under 28 brooders in 1930 was 12.3 per cent and in 1931 with 14 brooders was 16.0 per cent while the average of the entire group of 48 was 12.9 per cent.

Inspection of the distribution of mortality by flocks (Table II) shows that 24 or one-half of the entire number had a mortality of less than 10 per cent and 13, or more than one-half of the remaining group, from 10 to 20 per cent, 3 from 20 to 30 per cent, 3 from 30 to 50 per cent, and 5 had 50 per cent or more. In the case of two brooders, with more than 50 per cent loss in 1931, the presence of Pullorum disease was definitely established by veterinarians of Purdue University and the State Veterinarian's office.

TABLE II.—MORTALITY OF CHICKS[1]

Year	1929	1930	1931	All
Less than 10 per cent	4	14	6	24
Ten to 20 per cent	1	7	5	13
Twenty to 30 per cent	0	3	0	3
Thirty to 50 per cent	1	2	0	3
More than 50 per cent	0	2	3	5

[1] Figures denote numbers of flock.

Fig. 2. Electric Brooder Equipped with Two 500-watt Heating Elements.

Baby chicks with electric brooder on Clinton County farm. Two 500-watt heating elements, each controlled by a separate thermostat, are used in this brooder.

Consumption of Electric Energy

Six of the electric brooders metered were started during March, 12 from April 1 to 15, 19 from April 16 to 30, and 11 after May 1. It would seem from the data obtained that greater consumption per chick raised may be expected for brooding started early in March than that started in April. Of the six brooders started in March, three used between one-half and one kilowatt-hour per chick raised, while the other three exceeded one kilowatt-hour, the average for the entire group of 48 being 0.456 kilowatt-hour. In the case of those exceeding one kilowatt-hour two of the three brooders were those in which Pullorum disease was identified.

Of the five brooders, in which more than one kilowatt-hour per chick raised was used, the mortality in four of them exceeded 50 per cent and that of the fifth was 32 per cent. This would indicate that higher current consumption and consequently higher cost per chick raised is to be expected with high mortality.

TABLE III.—KILOWATT-HOURS USED PER CHICK RAISED[1]

Year	1929	1930	1931	All
Less than one-fourth	1	6	0	7
One-fourth to one-half	4	13	4	21
One-half to one	0	7	8	15
More than one	1	2	2	5

[1] Figures denote numbers of flocks.

The operator of the brooder is probably the most important factor affecting the amount of current consumed by an electric brooder, as revealed from the data obtained. Brooders of the same make started at the same time and operated for the same period with equal numbers of chicks vary widely in consumption of electric current indicating that the difference must be attributed to the operator. It would seem therefore that careful operation would result in lower current consumption.

Success with brooding chicks depends upon several factors besides the brooder stove. The Agricultural Extension Bulletin No. 177 recommends six important practices: Clean chicks, clean ground, clean house, clean litter, clean feed, and clean management.

SUCKLING PIG LOSSES AND ANEMIA

L. P. DOYLE

The heavy death loss of pigs during the nursing period presents a serious problem for the swine producer. It has been estimated that at least one-fourth of the pigs farrowed die before they are weaned. Strangely enough, the death losses have increased with the use of some of the modern methods of raising swine. For example, it has been a common occurrence for farmers to find that their efforts to raise pigs in modern hog houses have often been much less successful than were their efforts under more primitive conditions where less expensive equipment was used.

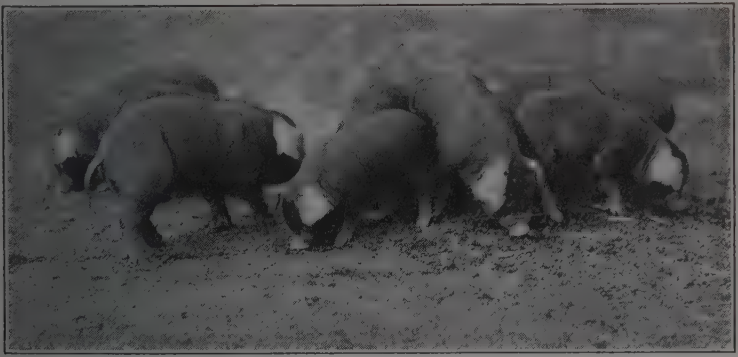

Figure 1.—A litter of anemic pigs, three weeks old. These pigs had been kept inside of a central hog house continuously since they were born. Figure 2 shows a more advanced stage of anemia in some of these same pigs.

In a series of experiments at the Purdue Agricultural Experiment Station, it was found that anemia in suckling pigs was intimately associated with a high death rate. In these experiments approximately 60 per cent of the anemic pigs died when from one to eight weeks of age, while only 4 per cent of the non-anemic animals died during the same age period. This work at Purdue

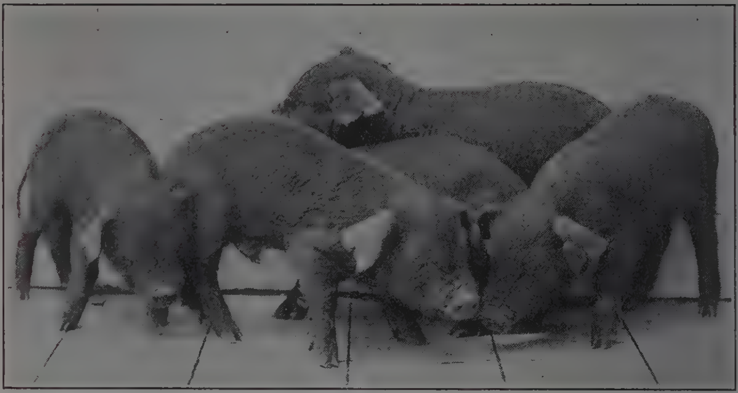

Figure 2.—The surviving pigs in the anemic litter shown in Figure 1. Almost one-h of the litter died when from three to five weeks old.

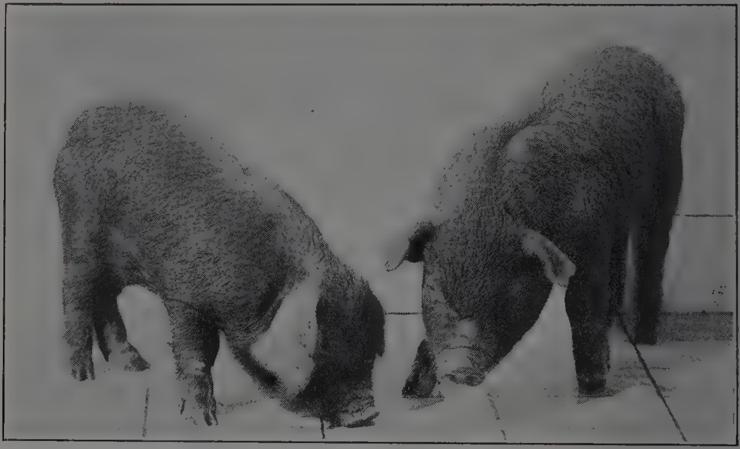

Figure 3.—Two anemic pigs. The one at the right is still in fair flesh, but it shows t lack of stamina which results from anemia.

was the first in the United States to call attention to the occurrence of anemia in pigs. Since the discovery of anemia in this country, Experiment Station workers in several states have turned their attention to the disease, and have found it to be an important cause of pig losses. It is interesting to note that anemia in pigs was definitely identified more than 40 years ago in Germany. At that time it became so destructive that swine-raising had to be abandoned in certain regions. The disease has also been recognized in England. The occurrence of anemia undoubtedly accounts for a large portion of the disappointing results which have followed efforts to raise pigs inside of barns or central hog houses. The investigations made at Purdue showed that a severe anemia was often ten times as prevalent in pigs which were kept inside as it was in those kept outside.

Anemia may be defined as an impoverished condition of the blood in which there is a deficiency in the number and quality of red blood cells. It is especially likely to develop in suckling pigs which are kept inside until they are ten days to four or five weeks of age. The disease sometimes occurs in pigs at birth, particularly when the pigs are farrowed by sows which have not been properly fed and managed during the gestation period.

The cause of anemia is the failure to supply the pigs with what is needed for the normal production of blood. The sow's milk is lacking in materials essential for normal blood formation, consequently, if the young pigs do not store up enough blood-building materials before they are born, anemia will develop during the nursing period unless something is supplied in addition to the mother's milk. A way has not yet been found to supply the necessary blood-forming materials through the milk of the sow.

The symptoms of anemia are quite characteristic, particularly in pigs which are from two to six weeks of age. In animals only a few days old the symptoms may not be so well defined. As a rule the pigs which become anemic are at first fat and make rapid gains in weight. In fact, the animals which make the most rapid gains up until the time they are four or five weeks of age are usually the ones which become most severely anemic if they subsist on milk alone. Anemic pigs, even though they appear well nourished, lack stamina, quickly become exhausted when made to exert themselves, and show a labored, jerky breathing which is usually called "thumps." They frequently develop scours in which

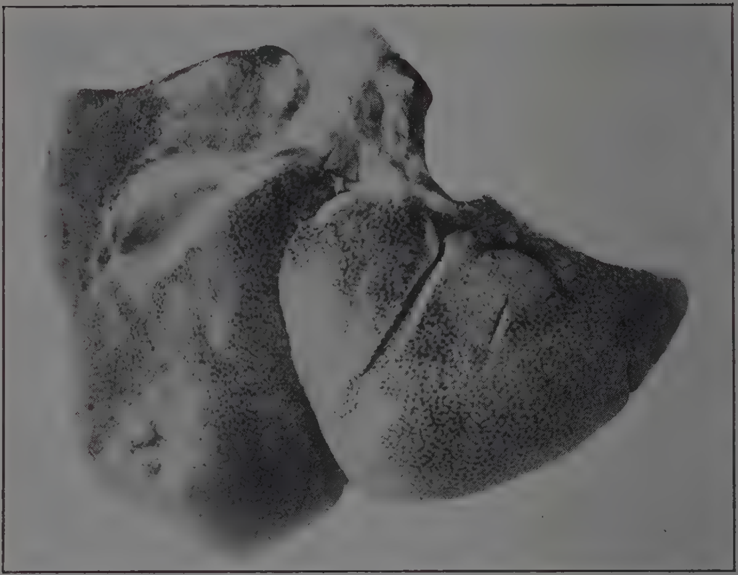

Figure 4.—The liver from a pig that died of anemia. It shows the grayish, mottled pearance which results from degenerative changes within the liver tissue.

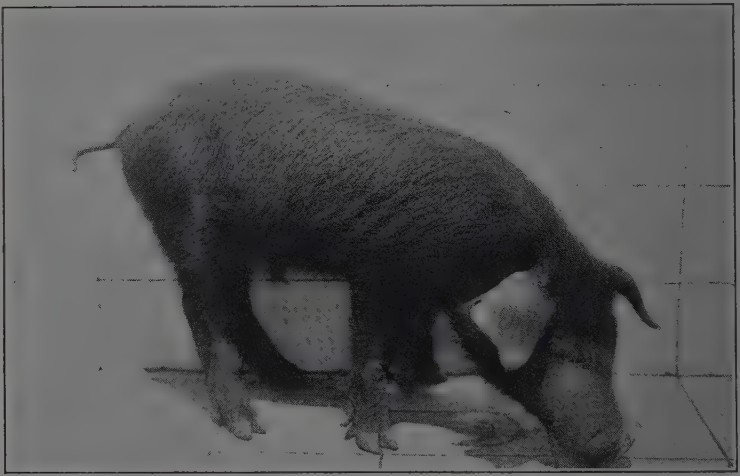

Figure 5.—An anemic pig which had been exposed to "bull nose" twenty days previou Note the diseased condition of the snout.

the bowel discharges are pale yellow or whitish in color. As the disease progresses, the pigs become listless and a paleness or pallidness becomes apparent in the skins of white and of red animals. This paleness can best be seen in the ears and on the under side of the body. A good many of the affected pigs develop a thickening along the under side of the neck and about the ears.

If severe anemia continues for any length of time, the pigs become stunted in growth, develop a wrinkled skin and rough coat of hair and show all the characteristics of "runts." This lasting damage done by the anemia which occurs in the early part of a pig's life is an important way in which the disease causes financial loss to the hog raiser. The delayed damaging effect of anemia is well illustrated by the following experience of farmers: Pigs are kept inside of a central hog house or barn continuously until they are three, four or five weeks old, and are then turned out. During the time the pigs are kept inside they often make rapid gains and become fat and sleek. Soon after being turned out they "go to pieces"; that is, they cease to grow and become unthrifty. The farmer too frequently makes the mistake of assuming that turning the pigs out caused the damage. The fact is the damage was done by keeping the young animals inside and merely became manifest soon after they were turned out. It is important to recognize the fact that many pigs die quite suddenly of anemia while they are still fat. Whole litters sometimes die of the disease during the nursing period.

Anemia greatly increases the pig's susceptibility to certain infections. Experiments at Purdue showed that it is much easier to produce so-called bullnose in anemic pigs than in non-anemic ones.

Fatal anemia in the young pig affects some of the internal organs and tissues in a very characteristic way. A post mortem examination of a pig which has died of anemia shows the following disease changes: The blood and muscles are pale and the heart is dilated so as to partially crowd the lungs from their normal position. The liver is often somewhat enlarged and nearly always shows fine, grayish mottling on the surface. There is usually an increased amount of fluid in the abdominal cavity, and often in the thoracic cavity. The spleen is sometimes enlarged. An experienced veterinarian can readily recognize anemia by the symptoms and post mortem findings. It is well to remember that some of

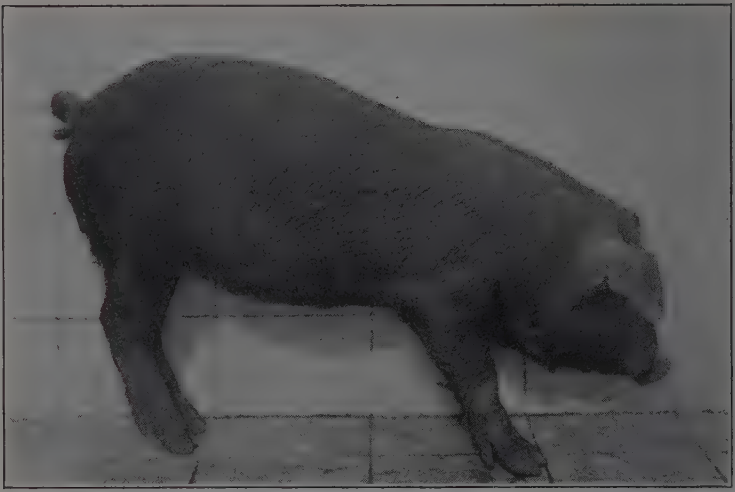

Figure 6.—A non-anemic pig, litter mate of the one shown in Figure 5, which had be exposed to "bull nose" twenty days previously. This pig was able to successfully resist t infection which caused bull nose in its anemic litter mate.

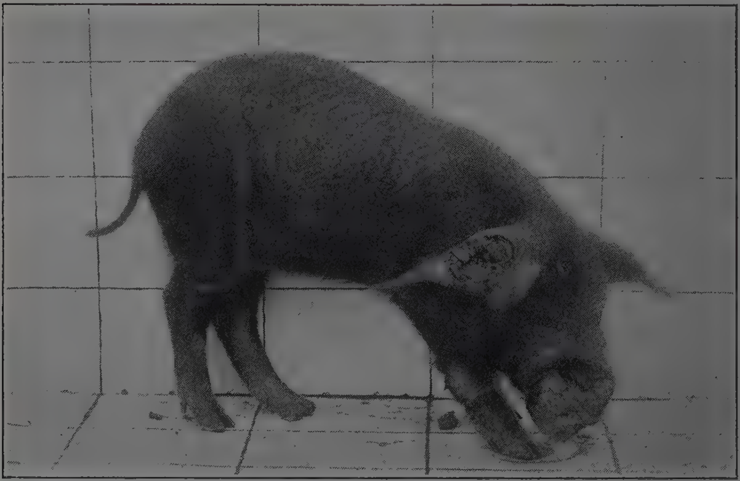

Figure 7.—Another anemic pig which had been exposed to the infection causing "bull nose This pig developed a pronounced form of "Necrobacillosis" of the ear and snout, while no anemic pigs which were exposed in the same way remained healthy.

the symptoms of anemia, such as scours and thumps, may also occur in other diseases.

The remedy for anemia is prevention. Preventive measures are even more important with anemia than with some other diseases. Ordinarily it is not possible to feed and manage the brood sow during the gestation period in such a way as to consistently prevent anemia in the young pigs which are kept inside for three or four weeks and not fed anything but the sow's milk. Anemia has been observed at birth in pigs farrowed by sows which had been in feed ots during the gestation period. It has also been found at birth n the pigs of sows which had been fed liberally on fattening rations even though the sows were on range during the gestation period. It is important to remember, however, that supplying good range for the sows and feeding an adequate ration without overfeeding during the gestation period are important steps toward nsuring vigorous pigs at farrowing time. If these pigs are then given access to outside conditions, particularly to blue grass sod, within the first week after being farrowed, they will almost invariably be amply protected against anemia, unless inclement weather causes the pigs to remain inside of the shelter house too much of the time.

The beneficial effect of allowing young pigs to have access to blue grass pasture was well shown by the results of the following experiment:* Twenty-two pregnant gilts which had been kept in dry lots during the gestation period were divided into two groups of eleven each. Both groups farrowed inside of a central hog house with a concrete floor. One group of sows and their pigs were kept nside the hog house continuously until the pigs were four weeks old. The other group of sows and their pigs were put outside when the pigs were from three to six days old. The sows which were put outside were kept in small pens with cinder floors and provided with individual houses for shelter. The pigs, however, were llowed to run over a small plat of blue grass sod. At four weeks of age the pigs which had been allowed to run on blue grass sod had nearly three times as much hemoglobin (red coloring matter) n their blood as the ones which had been kept inside the central hog house. The majority of the pigs which were kept inside were anemic before the end of four weeks.

---

* Professor C. M. Vestal of the Animal Husbandry Department, generously cooperated in arrying out this experiment.

Pigs are sometimes farrowed during the winter or early sprin when the weather is so cold or stormy that the young animals ca not be put out of doors. In such instances the placing of piec of blue grass sod in the pens where the pigs can eat it is qui effective in preventing anemia. It is essential that the pigs e some of the sod in order to obtain the beneficial effects. Sometim it is necessary to confine the pigs in a small portion of the pe with the sod for a few hours each day in order to induce them form the habit of eating the sod. Rich soil which is free from so when placed in the pens with the young pigs, is also helpful preventing anemia. However, it is better to use sod because youn pigs usually eat the sod much more readily than any other kind solid material. The sod does not necessarily need to be blue gras any other sod which is readily eaten by the young pigs should equally satisfactory.

Teaching the pigs to eat solid food as young as possible is great aid in reducing the losses due to anemia. Young anima which are only slightly affected by anemia make very satisfacto recoveries soon after they begin to eat a good ration.

How to Prevent Anemia in Pigs

(1) Provide a good range, preferably on sod, for the brood sow duri the gestation period; and feed an adequate ration but avoid overfeeding:

(2) Whenever possible, put the sow and pigs out on clean sod within c week after farrowing.

(3) If it is necessary to keep the pigs inside, put blue grass or so other good sod in the pens where the young pigs can have access to it—beg ning when the pigs are three to four days old.

The Indiana tag gives valuable information to the purchasers of commercial feed.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular contains a condensed report of commercial feed inspection in Indiana for the year 1931.

From the sale of tags it is estimated that 322,125 tons of commercial feeding stuffs with a retail value of $11,939,153 were sold in Indiana in 1931. The inspectors of the State Chemist department secured 2,804 samples, or approximately one sample for each 115 tons of feed sold in this state.

All of the 2,804 samples were examined microscopically and 2,420 of them were analyzed chemically. It was found that 85 per cent of the samples were equal to or better than the manufacturer's guarantee as declared on the official tag.

Of the 431 samples incorrectly guaranteed, 271 of them would be classed as seriously deficient or misbranded and sold in violation of the law. Shipments not tagged or seriously deficient were withdrawn from sale and manufacturers relabeled such feeds correctly and made refunds to the agents and consumers.

COMMERCIAL FEEDING STUFFS

H. R. KRAYBILL, State Chemist

O. S. ROBERTS, P. B. CURTIS, C. C. YUND, G. E. HALLIDAY, D. M. DOTY

Before a commercial feeding stuff may be legally sold or offered for sale in Indiana it is necessary that the feed be registered with the State Chemist, Purdue University Agricultural Experiment Station and that each package be properly labeled with an Indiana State Chemist tag. This is in accordance with the provisions of the Indiana Feeding Stuffs law passed in 1907 and amended in 1909. The object of this law is to have the feed in the bag correctly described on the Official Indiana State Chemist tag so that the purchaser may know just what kind of feed he is buying. The tag states the manufacturer's minimum guarantees for crude protein and crude fat, a maximum guarantee for crude fiber and the specific name of each ingredient contained in the feed. This information serves as an excellent guide in estimating the feeding value of the material.

To determine the correctness of the feed manufacturer's guarantee, 2,804 samples of commercial feeding stuffs were collected from manufacturers, dealers and consumers in various parts of the state during the year 1931. One inspection sample was secured from approximately each 115 tons of commercial feed sold in Indiana. All of the 2,804 samples were examined microscopically and 2,420 of them were analyzed chemically for moisture, crude protein, crude fat, crude fiber and ash content. Fifty samples of mineral feed were analyzed for lime (CaO), phosphoric acid (P_2O_5) and salt (NaCl) content.

The year's inspection shows that 85 per cent of the samples were equal to or better than the manufacturer's guarantee, as compared to 80 per cent in 1930. Of the 2,804 samples collected 431 of them were found to be guaranteed incorrectly and 271 were classed as being seriously deficient or misbranded and not sold in accordance with the Indiana Feeding Stuffs Law.

Shipments found to be seriously deficient were removed from sale immediately and the manufacturers either replaced the shipments with feed up to guarantee or relabeled them with a correct guarantee. Where deficient feed had already been sold, refunds were made to the dealers and consumers. The sum of $327.52 was refunded on 50 shipments by 41 different feed manufacturers.

During 1931 upon the advice of the State Chemist 353.6 tons of feeding stuffs were withdrawn from sale on account of non-tagging, deficiency and other reasons (Table II). Of this amount 276.3 tons, representing 157 shipments, were removed because of absence of Indiana State tags.

Estimated Sales of Commercial Feeding Stuffs in 1931

The year 1931 was a difficult year in practically all lines of business and that of feed was no exception. Based on the sale of official tags by the State Chemist, it is estimated that 322,125 tons of commercial feeding stuffs with a retail value of $11,939,153 were sold in Indiana in 1931. Compared with the sales of 1930 this represents a decrease of 37 per cent in tonnage and a corresponding decrease of 51 per cent in expenditures.

The principal increases in tonnage (Table III) sold were for alfalfa products, animal by-products, dried and condensed milk products and soybean oil meal. In practically all of the remaining classes of feed the tonnage dropped enormously. Especially, was this true of hominy feed and ready mixed feeds such as poultry mashes, poultry scratch feeds, cattle and dairy feeds and hog and pig meals. Although this general class of ready mixed feeds showed a decided decrease in tonnage there was a marked increase in the number of registrations of ready mixed protein supplements. In general it appears that the farmer was more interested in buying feeds to supplement his home grown grains than in purchasing prepared complete feeds.

Attention!

The official Indiana tag required by the Indiana Feeding Stuffs law bears the facsimile signature of the State Chemist and contains the manufacturer's guarantee.

Manufacturers or distributors should not neglect to attach these tags to each and every bag of feed shipped into Indiana in order to protect their dealers. The only products exempt are unmixed whole seeds and unmixed meals made directly from the entire grains.

When commercial feedings stuffs are sold in bulk either in carload lots or in pound lots from bags, barrels or other original containers, a tag or label must be delivered to the purchaser with each 100 pounds or fraction thereof.

Dealers and consumers should not accept any shipment or purchase without State Chemist tags or with such tags showing alterations. When such a shipment is received it should not be accepted until official Indiana tags are furnished to cover it.

Dealers and farmers should represent and purchase from manufacturers whose records show that they are complying with the law both in regard to labeling and maintaining guarantees of composition and ingredients. Table V "Summary of Feed Inspection" gives a record of the standing of each feed manufacturer for the year 1931.

Dealers and consumers are requested not to send miscellaneous samples of feed to the State Chemist without giving full information as to name of manufacturer, brand name, amount on hand and reasons for desiring an analysis. This also includes samples of feed suspected of having caused ill effects on animals or poultry. If sufficient quantity of such feed is on hand perhaps an official sample can be drawn under the direction of the State Chemist.

Manufacturers having difficulty in computing proper guarantees for their feed formulas may follow the following procedure as an example.

Method for Calculating Chemical Analysis Guarantee of a Mixed Feed

Ingredients in Batch of Feed	Pounds	Pounds of Fat	Pounds of Protein	Pounds of Fiber
Ground yellow corn	500	20.00	47.50	10.00
Soft wheat bran	200	7.00	29.00	16.00
Wheat middlings	200	7.00	31.00	12.00
Meat scraps 50% protein	100	6.00	50.00	3.00
Dried buttermilk	25	1.37	7.50	....
Alfalfa leaf meal	75	1.88	15.00	13.50
	1,100	43.25	180.00	54.50

Explanation—

(1) List the ingredients and amount of each used in batch.

(2) By using the information in Table I calculate the number of pounds of fat, protein and fiber furnished by each ingredient.
Example—500 lbs. of corn x 4.0% fat in corn = 20.00 lbs. of fat in 500 lbs. of corn.

(3) The sum of each column gives the total number of pounds of fat, protein and fiber in the particular batch.

(4) By dividing each total by the total pounds in the batch, the percentages of fat, protein and fiber are obtained.

Example— $\frac{43.25 \times 100}{1100} = 3.9\%$ fat

$\frac{180.00 \times 100}{1100} = 16.3\%$ protein

$\frac{54.50 \times 100}{1100} = 4.9\%$ fiber

From these percentages a safe guarantee would be 3.5% fat, 16.0% protein and 5.0% fiber.

Mineral Feeds

Mixed feeds containing both feed and more than 5 per cent of mineral ingredients require, in addition to the usual declaration of the chemical feed analysis, a declaration of each ingredient contained therein and the minimum percentages of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present. If minerals predominate in the mixture, the usual declaration of the chemical feed analysis, with the exception of protein, may be omitted.

Mineral feeds containing no organic ingredient do not require the usual chemical feed guarantee, but do require a declaration of each ingredient contained therein and the minimum percentage of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present.

That the mineral ingredients be stated in the common English terms, if any such terms exist.

It being impossible to classify separately the drug ingredients and the mineral ingredients, be it resolved:*

(1) That all mixtures containing mineral ingredients generally regarded as dietary factors essential for the normal nutrition of animals and which are sold or represented for the primary purpose of supplying these minerals as additions to rations in which these same mineral factors may be deficient, be classified as mineral feeds.

(2) That all other preparations which are sold or represented primarily for the cure, mitigation or prevention of disease be classified by this Association as drugs, medicines or specifics.

Manufacturers of mineral feeds who do not know just what guarantees of lime (CaO), phosphoric acid (P_2O_5), iodine (I) and salt (NaCl) to use for their particular formula are invited to write to the State Chemist Department for information regarding this matter.

Detailed information pertaining to the provisions of the Indiana Feeding Stuffs law will be gladly furnished upon request made to the State Chemist.

Explanation of Terms used in the Analysis of Feeding Stuffs

Moisture is the varying quantity of water occurring in feeding stuffs which can be driven off by heat at the temperature of boiling water. The amount of water present varies with the temperature, moisture content of the air, process of manufacture and the character of the substance. In most concentrates this value ranges from five to fifteen per cent.

Crude Fat consists mainly of fats and oils with small amounts of waxes, resins, coloring matter and similar substances, dissolved from feeding stuffs by dry ether. In calculating the heat and energy value of a feed, the fat is considered 2.25 times greater than that of either carbohydrates or protein.

Crude Protein is the term applied to the nitrogenous constituents of a feeding stuff. It is obtained by multiplying the total nitrogen by 6.25. Protein is the most important as wel as the most costly constituent in a feed. Plants have the power of building up protein from the inorganic elements o the soil and air while animals must secure their protein from the plants or other animals. The plant proteins contain varying amounts of the essential amino acids, therefore it is necessary to carefully select a variety of feeds which will furnish the essential amino acids economically.

---

* Adopted by the Association of American Feed Control Officials.

Crude Fiber is the woody portion of a feeding stuff, for th most part cellulose, and is insoluble in dilute acids and alkalis Most of the common seeds and grains contain very little fibe while the hulls, husks and stems are high in this constituent In poultry and swine, crude fiber when present in considerabl quantities exerts a retarding influence on the digestion of nutrients present.

Ash, the mineral matter of plants, is the residue left afte burning a feeding stuff at low redness. It consists chiefly o the phosphates, sulphates, chlorides and carbonates of sodium potassium, calcium and magnesium. The calcium and phosphorus are absolutely essential for the proper nutrition of th animal.

Nitrogen Free Extract consists of sugars, starches, pentoses, non-nitrogenous organic acids, etc., and is determine by subtracting the sum of moisture, crude fat, crude protein crude fiber and ash from 100.

Carbohydrates is the sum of the crude fiber and Nitrogen free extract.

TABLE I—AVERAGE ANALYSIS OF CEREALS AND BY-PRODUCTS

Material	Description of	Pounds in One Hundred		
		Crude Fat	Crude Protein	Crude Fiber
Alfalfa meal	Entire ground hay	1.5	13.0	33.0
Alfalfa leaf meal	Largely alfalfa leaves	2.5	20.0	18.0
Barley	Whole or ground	1.8	11.0	6.0
Beet pulp	Dried	0.9	8.5	18.0
Blood (dried)	Blood meal	0.5	80.0	none
Bone (raw)	Raw bone	3.0	20.0	1.0
Bone (steamed)	Steamed bone	0.5	6.0	1.0
Brewers' dried grains	From manufacture of beer	6.0	26.0	15.0
Buckwheat	Whole or ground	2.2	10.0	10.0
Buckwheat mixed feed	Entire product from manufacture of buckwheat flour	3.2	12.0	28.0
Buckwheat middlings	Entire product from manufacture of buckwheat flour, except the hulls	7.3	28.8	6.4
Buttermilk (dried)	Dried buttermilk	5.5	30.0	none
Buttermilk (condensed)	Condensed buttermilk	2.0	10.0	none
Cane seed	(Sorghum) removed from head and cleaned	2.5	9.0	2.5
Charcoal	Charcoal	none	none	90.0
Cob meal	Ground corn cob	0.5	2.0	31.0
Cocoanut oil meal	Dried cocoanut meats with partial extraction of oil	8.0	22.0	9.0
Corn	Old corn No. 2	4.0	9.5	2.0
Corn and cob meal	Ear corn (old)	3.5	8.0	8.0
Corn bran	Containing little corn germ	2.5	7.0	10.0
Corn mill feed	Corn bran germ and some meal from manufacture of meal or corn flour	7.4	11.0	4.2
Corn feed meal	Manufacture of cracked corn	3.5	9.0	2.0
Corn germ oil meal	Corn germ with part of the oil removed	8.0	20.0	8.0
Corn gluten feed	Remains after the larger part of starch and germ is removed	2.0	25.0	7.0
Corn gluten meal	From manufacture of corn starch and glucose	1.0	42.0	2.0
Corn screenings	Small and broken grains of corn, small pieces cob, etc., removed from shelled corn	2.7	8.6	8.6
Cottonseed meal (prime quality)	Sold as 36 per cent protein	6.0	36.0	14.0
Cottonseed meal (prime quality)	Sold as 41 per cent protein	6.0	41.0	12.0
Cottonseed meal (prime quality)	Sold as 43 per cent protein	6.0	43.0	10.0
Cottonseed feed	Below 36 per cent protein	4.0	22.8	22.0
Cottonseed hulls	Contains trace of lint and meal adhering	1.8	4.6	38.0
Cowpea	Seeds, pods removed	1.4	20.8	4.1
Distillers' grain (dried)	From corn or rye	9.0	27.0	12.0
Emmer	Often called spelt	2.0	11.5	10.0
Fish meal	Dried ground tissues of fish with or without the extraction of part of the oil	6.0	55.0	2.0
Flaxseed	Whole grain or meal without extraction of oil	32.0	22.0	7.0
Flax plant by-product	Shives, pods, etc.	2.1	15.0	31.0
Flaxseed screenings	Small and broken grains, flaxseed, weed seed and other foreign material cleaned from flaxseed	8.0	14.0	14.0

TABLE I—Continued

Material	Description of	Pounds in One Hundred		
		Crude Fat	Crude Protein	Crude Fiber
Hominy feed, meal or chop	Manufacture of hominy grits or meal by degerminator process	6.0	11.0	6.0
Kafir corn	Milo	2.5	10.0	2.5
Kelp (dried)	Ground dried kelp	1.0	6.0	10.0
Linseed meal (old process)	Oil extracted by pressure	6.0	34.0	8.0
Malt sprouts	Sprout of the barley grain	1.3	27.9	12.1
Meat scraps	Ground dry rendered residue from animal tissues	6.0	50.0	3.0
Millet	Italian millet seed	3.9	10.3	9.4
Milo	Whole or ground	2.5	10.7	2.5
Molasses	From beets	none	3.0	....
Molasses	Blackstrap from cane	none	3.0	....
Oats	Ground or whole	4.0	11.0	11.0
Oat-clipped by-product	Clippings	2.0	9.0	30.0
Oat-groats	Kernels of oat berry	6.5	15.0	2.0
Oat hulls	Oat hulls	1.5	4.0	32.0
Oat meal mill by-product	Oat hulls and oat shorts	1.5	6.0	28.0
Oat middlings	Floury portion of oat groat	5.0	15.0	5.0
Peanut oil feed	Peanut meats and peanut hulls	6.0	30.0	25.0
Peanut oil meal	Residue after the extraction of part of the oil from peanut kernels	6.0	40.0	6.0
Peanut shells	Whole or finely ground	1.2	5.5	70.9
Rice bran	Cuticle layer beneath hull	12.0	12.0	12.0
Rye	Rye	1.5	11.0	2.0
Rye feed	Rye feed	3.5	16.0	5.0
Skimmed milk (dried)	Dried skimmed milk	0.5	30.0	none
Soybean	Seed pods removed	19.0	35.0	5.0
Soybean oil meal	Ground	6.0	40.0	6.0
Sunflower seed	Whole or ground	19.0	16.0	30.0
Tankage (digester)	60 per cent reinforced with concentrated tank water or dried blood	6.0	60.0	3.0
Unscreened flaxseed oil feed	Flaxseed meal and flaxseed screenings	6.0	30.0	9.0
Velvet bean feed	Velvet beans and pods	4.0	19.0	17.0
Wheat	Whole or ground	1.9	11.9	2.4
Wheat bran (soft)	Wheat bran	3.5	14.5	8.0
Wheat bran (hard)	Wheat bran	4.0	16.0	10.0
Wheat middlings	Wheat middlings	3.5	15.5	6.0
Wheat standard middlings	With and without screenings	4.0	16.0	9.5
Wheat red dog flour	Red dog flour	3.5	15.0	4.0
Wheat mixed feed and mill run screenings	Bran, middlings, red dog flour and screenings	3.5	15.0	8.0
Whey (dried)	Dried whey	0.5	12.0	none

DEFINITIONS OF FEEDING STUFFS*

Alfalfa Products

Chopped Alfalfa is the entire alfalfa hay, chopped and not ground finely enough to become a meal. It must not contain an admixture of alfalfa straw or other foreign material.

Alfalfa Meal is the product obtained from the grinding of the entire alfalfa hay, without the addition of any alfalfa stems, alfalfa straw or foreign material, or the abstraction of leaves. It must be reasonably free from other crop plants and weeds, and must not contain more than 33 per cent of crude fibre.

Alfalfa Leaf Meal is the ground product consisting chiefly of leafy materials separated from alfalfa hay. It must be reasonably free from other crop plants and weeds and must not contain more than 18 per cent of crude fibre.

Alfalfa Stem Meal is the ground product remaining after the separation of the leafy material from alfalfa hay or meal. It must be reasonably free from other crop plants and weeds.

Animal By-Products

Blood Meal is ground, dried blood.

Blood Flour is dried blood, prepared by special processes and reduced to a fine powder.

Digester Tankage, Meat Meal Tankage or Feeding Tankage is the residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry-rendering or a mixture of the products made suitable by drying and grinding. When these products contain more than 10 per cent phosphorus (P_2O_5) they shall be designated Digester Tankage with Bone, Meat and Bone Meal Digester Tankage, Meat and Bone Meal Tankage, or Feeding Tankage with Bone. If they bear a name descriptive of their kind, composition or origin they must correspond thereto.

Meat Scraps is the ground dry rendered residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice. When this product contains more than 10 per cent phosphorus (P_2O_5), it shall be designated Meat and Bone Scrap. If they bear a name descriptive of their kind, composition or origin they must correspond thereto.

---

* These definitions have been adopted by the Association of American Feed Control Officials.

Raw Bone Meal is the dried, ground product suitable for animal feeding, obtained by cooking in water at atmospheric pressure, undecomposed bone, just enough to remove excess fat and meat. It must not contain less than 23 per cent of protein.

Steamed Bone Meal is the dried, ground product suitable for animal feeding obtained by cooking bones with steam under pressure.

Special Steamed Bone Meal is the dried, ground product suitable for animal feeding obtained by cooking dried bone after the removal of grease and meat fibre with steam under pressure in the process of obtaining gelatine or glue.

Brewers' and Distillers' Products

Brewers' Dried Grains are the properly dried residue from cereals obtained in the manufacture of beer.

Distillers' Dried Grains are the dried residue from cereals obtained in the manufacture of alcohol and distilled liquors. The product shall bear the designation indicating the cereal predominating.

Distillers' Corn Solubles, a by-product from the manufacture of alcohol from corn, is a mash liquor concentrated after the removal of the alcohol and wet grains.

Distillers' Rye Solubles, a by-product from the manufacture of alcohol from rye, is a mash liquor concentrated after the removal of the alcohol and wet grains.

Distillers' Corn and Rye Solubles, a by-product from the manufacture of alcohol from corn and rye, is a mash liquor concentrated after the removal of the alcohol and wet grains.

Malt Sprouts are the sprouts of the barley grain obtained in the malting process. Sprouts derived from any other malted cereal must be designated by the name of that cereal.

Yeast or Vinegar Dried Grains are the properly dried residue from the mixture of cereals, malt and malt sprouts (sometimes cottonseed meal) obtained in the manufacture of yeast or vinegar, and consists of corn or corn and rye from which most of the starch has been extracted, together with malt added during the manufacturing process to change the starch to sugars, and malt sprouts (sometimes cottonseed meal) added during the manufacturing process to aid in filtering the residue from the wort and serve as a source of food supply for the yeast.

Buckwheat Products

Buckwheat Shorts or Buckwheat Middlings are that portion of the buckwheat grain immediately inside the hull after separation from the flour.

Corn Products

Corn Meal (Feeding) is finely ground, unbolted corn.

Corn Bran is the outer coating of the corn kernel, with little or no starchy part or germ.

Corn Feed Meal is the fine siftings obtained in the manufacture of screened corn chop, screened ground corn or screened cracked corn, with or without its aspiration products added.

Corn Chop, Ground Corn or Cracked Corn is the entire product made by grinding, cutting or chopping the grains of sound Indian corn, and may be fine, medium or coarse, and must not contain more than 4 per cent of foreign material.

Screened Corn Chop, Screened Ground Corn, or Screened Cracked Corn is the coarse portion of corn chop, ground corn or cracked corn from which most of the fine particles have been removed, and must not contain more than 4 per cent of foreign material.

Corn Grits, Hominy Grits are the fine or medium sized, hard flinty portions of Indian corn containing little or no bran or germ.

Ear Corn Chops is corn and cob chopped, without the husk, with no greater proportion of cob than occurs in the ear corn in its natural state.

Corn Gluten Meal is that part of commercial shelled corn that remains after the separation of the larger part of the starch, the germ and the bran, by the processes employed in the manufacture of corn starch. It may or may not contain corn solubles.

Corn Gluten Feed is that part of commercial shelled corn that remains after the separation of the larger part of the starch and the germs by the processes employed in the manufacture of corn starch. It may or may not contain corn solubles.

Maltose Process Corn Gluten Feed is the dried residue from degermed corn, after removal of starch in the manufacture of malt syrup.

Hominy Feed, Hominy Meal or Hominy Chop is the kiln-dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the white corn kernel obtained in the manufacture of hominy, hominy grits, and cornmeal by the degerming process.

Yellow Hominy Feed, Yellow Hominy Meal or Yellow Hominy Chop is a kiln dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the yellow corn kernel obtained in the manufacture of yellow hominy grits and yellow corn meal by the degerming process.

Corn Oil Cake consists of the corn germ from which part of the oil has been pressed and is the product obtained in the wet milling process of manufacture of corn starch, corn syrup, and other corn products.

Corn Oil Meal is ground corn oil cake.

Corn Germ Cake consists of corn germ with other parts of the corn kernel from which part of the oil has been pressed, and is the product obtained in the dry milling process of manufacture of corn meal, corn grits, hominy feed, and other corn products.

Corn Germ Meal is ground corn germ cake.

Corn Screenings are the small light grains of corn, parts of grains of corn and/or other cereals, and other materials having feeding value, obtained by screening shelled corn, excluding sand, dirt and other similar inert materials.

Cottonseed Products

Cottonseed Meal is a product of the cottonseed only, composed principally of the kernel with such portion of the hull as is necessary in the manufacture of oil; provided that nothing shall be recognized as cottonseed meal that does not conform to the foregoing definition and that does not contain at least 36 per cent of protein. Cottonseed meal shall be graded and classed as follows:

1. **Cottonseed Meal,** Prime Quality. Cottonseed meal, prime quality, must be finely ground, not necessarily bolted, of sweet odor, reasonably bright in color, yellowish, not brown or reddish, free from excessive lint, and shall contain not less than 36 per cent of protein. It shall be designated and sold according to its protein content. Cottonseed meal with 36 per cent of protein shall be termed "36 per cent Protein Cottonseed Meal, Prime Quality," and higher grades similarly designated (as "43 per cent Protein Cottonseed Meal, Prime Quality"), etc.

2. **Cottonseed Meal,** Off Quality. Cottonseed meal not fulfilling the above requirements as to color, odor and texture shall be graded "36 per cent Protein Cottonseed Meal, Off Quality," and higher grades similarly designated.

Cottonseed Feed is a mixture of cottonseed meal and cottonseed hulls, containing less than 36 per cent of protein.

Cold, Pressed Cottonseed is the product obtained from the subjection of the whole undecorticated cottonseed to the cold pressure process for the extraction of oil and includes the entire cottonseed less the oil extracted.

Ground Cold Pressed Cottonseed is the product obtained by grinding cold pressed cottonseed.

Linseed and Flax Products

Linseed Cake or Meal is oil cake or meal made from flaxseed; provided that the final product shall contain less than 6 per cent of weed seeds and other foreign materials and; provided further, that no portion of the stated 6 per cent of weed seeds and other foreign materials shall be deliberately added.

Old Process Oil Meal, Old Process Linseed Meal is oil meal as defined or linseed meal as defined produced by crushing, cooking and hydraulic pressure.

New Process Oil Meal, New Process Linseed Meal is oil meal as defined or linseed meal as defined produced by crushing, heating and the use of solvents.

Flax Plant By-Products is that portion of the flax plant remaining after the separation of the seed, the bast fiber and a portion of the shives, and consists of flax shives, flax pods, broken and immature flax seeds, and the cortical tissues of the stem.

Ground Flaxseed or Flaxseed Meal is the product obtained by grinding flaxseed which has been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process; provided that the final product shall contain less than 4 per cent of weed seeds and other foreign materials, and; provided further, that no portion of the stated 4 per cent of weed seeds and other foreign materials shall be deliberately added.

Unscreened Flaxseed Oil Feed Cake is the product obtained by extraction of part of the oil from unscreened flaxseed by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents. The ingredients shall be stated as partially extracted flaxseed and foreign seeds (wheat, wild buckwheat, pigeon grass, wild mustard, etc.).

Ground Unscreened Flaxseed Oil Feed is the ground unscreened flaxseed oil feed cake.

Screenings Oil Feed is the ground product obtained after extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents from the smaller imperfect grains, weed seeds and other foreign materials, having feeding value, separated in cleaning the grain. The name of the grain from which the screenings are separated shall be prefixed to "screenings oil feed."

Oil Cake is the product obtained after the extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents, from seeds which have been screened and cleaned of weed seeds, and other foreign material by the most improved commercial process. When used alone the term "Oil Cake" shall be understood to designate linseed cake as defined. When used to cover any other products the name of the seed from which it is obtained shall be prefixed to the words "Oil Cake."

Oil Meal or Ground Oil Cake is oil cake ground to a meal.

Oat Products

Oat Hulls are the outer coverings of the oat.

Oat Middlings are the floury portions of the oat groat obtained in the milling of rolled oats.

Oat Shorts are the covering of the oat grain lying immediately inside the hull, being a fuzzy material carrying with it considerable portions of the fine floury part of the groat obtained in the milling of rolled oats.

Oat Chop, Ground Oats, Pulverized Oats, Crushed Oats and Crimped Oats consists of the entire product made by chopping, cutting, grinding, crushing or crimping oats.

Oat Groats are the kernels produced from cleaned and dried oats in the process of manufacturing oat meal.

Hulled Oats, Undried Oat Groats are the kernels produced from the undried grain in the process of hulling oats.

Oat Meal, Ground Oat Groats is the product produced by cutting, cracking or grinding oat groats.

Rolled Oat Groats (Rolled Oats) is the product obtained in the process of rolling oat groats.

Clipped Oat By-Products is the by-product obtained in the manufacture of clipped oats. It may contain the light chaffy material broken from the end of the hulls, empty hulls, light immature oats and dust. It must not contain an excessive amount of oat hulls.

Wheat Products

Wheat Bran is the coarse outer covering of the wheat kernel as separated from cleaned and scoured wheat in the usual process of commercial milling.

Standard Middlings consists mostly of fine particles of bran, germ and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and shall not contain more than 9.5 per cent crude fiber.

Flour Middlings shall consist of standard middlings and red dog flour combined in the proportions obtained in the usual process of milling and shall not contain more than 6.0 per cent crude fiber.

Wheat Red Dog, a by-product obtained in the usual commercial process of flour milling, consists principally of aleurone with small quantities of flour and fine bran particles and shall not contain more than 4.0 per cent crude fiber.

Wheat Low Grade Feed Flour, a by-product obtained in the usual commercial process of flour milling, consists principally of flour with small quantities of aleurone and fine bran particles and shall not contain more than 1.5 per cent crude fiber.

Wheat Bran and Standard Middlings consists of the two commodities as defined above, mixed in the proportions obtained in the usual process of commercial milling.

Hard Wheat Mixed Feed (Mill-run wheat feed) consists of pure wheat bran and flour middlings combined in the proportions obtained in the usual process of commercial milling. This product shall not contain more than 9.5 per cent crude fiber.

Brown Shorts (Red Shorts) consists mostly of the fine particles of bran, germ and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and shall not contain more than 7.5 per cent crude fiber.

Gray Shorts (Gray Middlings or Total Shorts) consists of the fine particles of the outer bran, the inner bran or bee-wing bran, the germ and the offal or fibrous materials obtained from the "tail of the mill." This product must be obtained in the usual process of commercial milling and shall not contain more than 6.0 per cent crude fiber.

White Shorts or White Middlings consists of a small portion of the fine bran particles and the germ and a large portion of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual process of flour milling and shall not contain more than 3.5 per cent crude fiber.

Wheat Mixed Feed (Mill-run wheat feed) consists of pure wheat bran and the gray or total shorts combined in the proportions obtained in the usual process of commercial milling. This product shall not contain more than 8.5 per cent crude fiber.

Screenings consists of the smaller imperfect grains, weed seeds, and other foreign materials, having feeding value, separated in cleaning the grain.

Scourings consists of such portions of the cuticle, brush, white caps, dust, smut and other materials as are separated from the grain in the usual commercial process of scouring.

(NOTE) If to any of the wheat or rye by-products feeds there should be added screenings or scourings—as above defined, either ground or unground, bolted or unbolted, such bran shall be so registered, labeled and sold as clearly to indicate this fact. The word "Screenings" or "Scourings" as the case may be, shall appear as part of the name or brand and shall be printed in the same size and face of type as the remainder of the brand name. When the word "Screenings" appears it is not necessary to show also on the labeling the word "Scourings."

Miscellaneous Products

Dried Beet Pulp is the dried residue from sugar beets which have been cleaned and freed from crown, leaves and sand, and which have been extracted in the process of manufacturing sugar.

Cocoanut Oil Meal or "Copra Oil Meal" is the ground residue from the extraction of part of the oil from the dried meat of the cocoanut.

Ivory Nut Meal is the ground waste material resulting from the manufacture of buttons and similar articles from the vegetable ivory nut.

Processed Garbage is composed of animal and vegetable waste from garbage collected sufficiently often that harmful decomposition has not set in and is separated from material such as crockery, glass, or similar material. Its odor must not be suggestive of the presence of decomposition and it must contain less than one per cent of glass. None of it shall contain knife like or needle like particles, and providing further, that the maximum percentage of glass be stated on the label when present in excess of one-fifth of one per cent.

Palm Kernel Oil Meal is the ground residue from the extraction of part of the oil by pressure or solvents from the kernel of the fruit of Elaeis guineensis or Elaeis malanococco.

Chop is a ground or chopped feed composed of one or more different cereals or by-products thereof. If it bears a name descriptive of the kind of cereals, it must be made exclusively of the entire grains of those cereals.

Head Chops consists of the entire head of the grain sorghums chopped, and should bear the name of the sorghum from which it is made. This includes, among others, kaffir head chops, milo head chops, feterita head chops, and sorghum head chops.

Head Stems consists of the head of the grain sorghums, from which the grain has been removed, and should bear the name of the sorghum from which it is made.

TENTATIVE DEFINITIONS

Table Scrap Meal is the properly cooked, dried and ground residue resulting from freshly collected hotel and house garbage from which all metal, crockery, glass, and other foreign material has been removed except in such traces as may unavoidably occur in good factory practice. The finished product must not be suggestive of material decomposition in odor. It must not contain any sharp, needle pointed pieces of glass and must not contain more than one-fifth of one per cent of finely ground glass or dull particles of glass.

Whole Pressed Cottonseed, Prime Quality, is the product resulting from subjecting the whole, sound, mature, clean undecorticated cottonseed to pressure for the extraction of oil, and includes the entire cottonseed less the oil extracted and the lint removed. It must be designated and sold according to its protein content.

Ground, Whole Pressed Cottonseed, Prime Quality, is whole pressed cottonseed, ground. It must be designated and sold according to its protein content.

Iodized Salt (Feeding) is common salt (NaCl) containing an alkaline iodide in quantity not less than 0.015 per cent iodine, uniformly distributed.

Hominy Feed or Meal is a mixture of corn bran, corn germ (with or without a partial extraction of the oil), a part of the starchy portion of either white or yellow corn kernels or mixture thereof, obtained in the manufacture of hominy, hominy grits or table meal, and contains not less than 5 per cent of fat. If prefixed with the words white or yellow the product must correspond thereto.

Oat Mill Feed (Oat Hulls, Oat Shorts, and Oat Middlings) is the entire by-product produced in the manufacture of oat groats and consists of oat hulls, oat shorts and oat middlings.

Milk Products

Dried Buttermilk (Feeding) is the product resulting from the removal of water from clean, sound buttermilk derived from natural cream, to which no foreign substances have been added, excepting such as are necessary and permitted in the manufacture of butter. It contains not more than 8 per cent of moisture, not more than 13 per cent of mineral matter (ash), and not less than 5 per cent butterfat, as determined by the Roese-Gottlieb method.

Dried Soured Skimmed Milk (Feeding) is the product resulting from the removal of water from clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not more than 8 per cent moisture.

Milk Sugar Feed (Dried Whey) is the by-product from the manufacture of cheese containing at least 70 per cent lactose (milk sugar).

Evaporated Soured Skimmed Milk (Feeding), **Concentrated Soured Skimmed Milk** (Feeding), **Condensed Soured Skimmed Milk** (Feeding) is the product resulting from the removal of a considerable portion of water from the clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not less than 27 per cent total solids.

Marine Products

Fish Meal (Feeding) is clean, dried, ground tissues of undecomposed whole fish and/or fish cuttings with or without the extraction of part of the oil, and contains not more than 3 per cent salt (NaCl).

Fish Residue Meal (Feeding) is the clean, undecomposed residue from the manufacture of glue from non-oily fish, and contains not more than 3 per cent salt (NaCl).

Crab Meal (Feeding) is prepared from the undecomposed waste of the crab industry and contains the shell, viscera and part or all of the flesh. It contains not less than 25 per cent protein and not more than 3 per cent salt (NaCl).

Shrimp Meal (Feeding) is prepared from the undecomposed waste of the shrimp industry and contains the head, hull and/or the whole shrimp and not more than 3 per cent salt (NaCl).

Fish Oils

Cod Liver Oil is the product obtained by extraction of part of the oil from cod livers.

Sardine Oil, Pilchard Oil is the product obtained by extraction of part of the oil from the whole Pacific sardine or pilchard or from cannery refuse of this species of fish.

Salmon Oil is the product obtained by extraction of part of the oil from the cannery refuse of salmon.

Tuna Oil is the product obtained by extraction of part of the oil from the cannery refuse of tuna.

Menhaden Oil is the product obtained by the extraction of part of the oil from whole Menhaden.

TABLE II—WITHDRAWALS FROM SALE

Number of Shipments Withdrawn From Sale	Number of Manufacturers Represented	Reasons for Withdrawal from Sale	Amount Withdrawn Tons
157	93	Not tagged	276.3
15	13	Deficient in crude protein	43.9
1	1	Deficient in crude protein and excess fiber	14.0
12	10	Misbranded	13.5
6	6	Mutilated tags	4.2
1	1	Deficient in crude fat and excess fiber	0.8
1	1	Deficient in crude fat and crude protein	0.5
1	1	Deficient in phosphoric acid	0.3
1	1	Deficient in crude fat	0.1
195	....	Totals	353.6

TABLE III—Estimated Sales of Commercial Feeding Stuffs in Indiana

Kind of Feed	Estimated Tons			Estimated Retail Values, Dollars	
	1929	1930	1931	1930	1931
Alfalfa meal and leaf meal	2,657	3,063	3,906	135,997	156,240
Animal by-products (Tankage, meat scraps, etc.)	26,094	27,750	32,719	1,709,400	1,328,391

TABLE IV—SUMMARY OF THE ANNUAL TONNAGE AND EXPENDITURES FOR COMMERCIAL FEEDING STUFFS SINCE 1911

Year	1911	1912	1913	1914	1915	1916	1917
Estimated sales, tons	179,000	196,752	217,689	271,751	270,339	317,664	379,152
Estimated retail value, dollars	5,056,906	6,371,571	6,406,645	8,461,751	8,221,684	10,316,516	21,700,101
Year	**1918**	**1919**	**1920**	**1921**	**1922**	**1923**	**1924**
Estimated sales, tons	439,152	506,958	390,078	283,256	340,197	389,971	419,441
Estimated retail value, dollars	26,717,086	33,013,463	27.014,049	11,716,745	14,244,175	18,026,682	19,720,313
Year	**1925**	**1926**	**1927**	**1928**	**1929**	**1930**	**1931**
Estimated sales, tons	408,713	337,298	440,534	524,476	498,887	512,096	322,125
Estimated retail value, dollars	20,945,026	16,837,512	24,173,605	29,818,566	26,491,777	24,293,652	11,939,153

TABLE V—SUMMARY OF FEED INSPECTION

January 1, 1931 to January 1, 1932

Name and Address of Manufacturer	Number of Samples Examined	Number of Samples Passed	Number of Samples not Passed	Number of Samples not Tagged
Abilene Flour Mill Co., Abilene, Kansas	1	1		
Abingdon Milling & Cattle Feeding Co., Abingdon, Ill.	2	2		
Acme-Evans Co., Indianapolis, Ind.	33	30	3	3
Allied Mills, Inc., Chicago, Ill.	59	58	1	8
American Maize Products Co., New York, N. Y.	3	3		1
American National Mineral Corp., Hillsboro, Ind.	8	6	2	
Amo Milling Co., Amo, Ind.	3	1	2	
Amos Pig Grow Tonic & Food Co., Kokomo, Ind.	6	3	2	1
Anchor Feed Co., Kokomo, Ind.	2	2		
Anchor Milling Co., Rochester, Ind.	10	8	2	
Angola Flour Mills, Angola, Ind.	4	3	1	
Angola Reduction Co., Angola, Ind.	1	1		
Arcady Farms Milling Co., Chicago, Ill.	17	13	3	2
Archer-Daniels-Midland Co., Minneapolis, Minn.	13	13		5
Armour & Co., Chicago, Ill.	24	22	2	
Armour Creameries, Chicago, Ill.	1	1		
Associated Feed Dealers of America, Inc., South Bend, Ind.	11	9	2	2
Aubrey & Co., Louisville, Ky.	4	4		1
Auburn Roller Mills, Auburn, Ind.	2	2		
Augenbaugh & Co., Everett, Waseca, Minn.	1	1		
Aukerman Bros.-Catey Co., Amboy, Ind.	10	10		
Aukerman Bros. Co., Peru, Ind.	14	13	1	
Aurora Farmers Supply Co., Aurora, Ind.	2	2		
Aurora Flour & Feed Co., Aurora, Ind.	7	7		
Aviston Milling Co., East St. Louis, Ill.	2	1		1
Badenoch Co., J. J., Chicago, Ill.	8	8		
Badger Grain & Feed Co., Inc., Milwaukee, Wis.	1	1		
Bahler Feed Co., Remington, Ind.	5	5		
Baker, Jesse I., Hagerstown, Ind.	4		4	
Ballard Packing Co., Marion, Ind.	2	1	1	
Bash & Co., C. E., Huntington, Ind.	5	5		
Bashore Feed Store & Hatchery, Silver Lake, Ind.	5	5		
Bashore Feed Store and Hatchery, Warsaw, Ind.	2	2		
Batesville Fertilizer Co., Batesville, Ind.	4	3	1	
Batesville Roller Mills, Batesville, Ind.	2	2		
Battle Creek Dog Food Co., Battle Creek, Mich.	2	2		
Bausback Fertilizer Co., Shelbyville, Ind.	5	5		
Bay Chemical Co., New Orleans, La.	1	1		
Beck Grain & Feed Co., Shelbyville, Ind.	9	7	2	
Bee Line, The, LaPorte, Ind.	6	6		3
Benz Co., The, Batesville, Ind.	1	1		
Berne Grain & Hay Co., Berne, Ind.	7	5	2	
Bickels Feed & Supply Store, Corydon, Ind.	3	3		
Bisbee Linseed Co., Chicago Heights, Ill.	13	13		1
Bishop Feed Line, LaPorte, Ind.	1	1		
Blackburn Milling Co., Omaha, Nebr.	1		1	
Blanton Milling Co., Indianapolis, Ind.	2	2		
Blatchford Calf Meal Co., Waukegan, Ill.	1	1		
Blish Milling Co., Seymour, Ind.	3	3		
Bloomington Milling Co., Bloomington, Ind.	1	1		
Bloomington Packing Co., Bloomington, Ind.	5	3	2	

TABLE V—Summary of Feed Inspection

January 1, 1931 to January 1, 1932

Name and Address of Manufacturer	Number of Samples Examined	Number of Samples Passed	Number of Samples not Passed	Number of Samples not Tagged
Blue River Reduction Co., Edinburg, Ind.	8	8	......	......
Board of Sanitary Commissioners, Indianapolis, Ind.	5	5	......	1
Bohnert & Son, A. M., Jasper, Ind.	1	1	......	......

Circular No. 190 April, 1932

UNIVERSITY OF AR
LIBRARY

COMMERCIAL FERTILIZERS

Unfertilized Fertilized

Effect of Fertilizer in Hastening the Maturity of Corn

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

The Indiana Fertilizer Law protects the purchaser of commercial fertilizers as well as the honest and efficient manufacturer, dealer and agent. This circular gives a detailed report of the inspection of commercial fertilizers sold in Indiana for the year 1931. In order to obtain maximum protection the consumer must read carefully and understand thoroughly the information on the state tag.

Purchasers of commercial fertilizer for the Fall of 1932 and the Spring of 1933 should read the paragraph entitled "SPECIALS" on page 5 of this circular.

Table 2 shows the tonnages of the different analyses for which there was the most demand. The tonnage sales of 2-12-6 were far above those of any other analysis. Over 80% of the total tonnage was confined to 33 grades while less than 20% was divided among 167 different grades. Considerable saving could be made by the manufacturers if the number of grades were materially reduced.

Approximately 131,512 tons of high grade and only 2,956 tons of low and medium grade mixed fertilizer were sold in Indiana in 1931.

The average content of actual plant food in all of the fertilizer sold in 1931 was 490 pounds per ton. The average analysis was 2.4% total nitrogen, 13.0% available phosphoric acid and 7.1% water soluble potash.

Sales of raw materials such as nitrogen salts, potash salts, superphosphates, bone products and raw rock phosphates were slightly higher while sales of mixtures of these in which the bulk of the tonnage is sold were decidedly less than last year.

There was an improvement in the number of samples which were found equal to the guarantee in every particular (Table 8).

Due to lack of funds the table giving the analyses of individual samples is omitted from the report this year. It is the intention to resume publication of this table in future publications as soon as funds are available.

COMMERCIAL FERTILIZERS

H. R. KRAYBILL, *State Chemist*

). S. ROBERTS O. W. FORD L. E. HORAT

M. H. THORNTON

From the sale of tags it is estimated that 170,777 tons of commercial ertilizer having a retail value of $5,504,088 were sold in Indiana in 1931. nspectors from the State Chemist department drew 1,396 official samples epresenting one sample for every 122 tons of fertilizer sold. Of these samples ,315 were equal to or above the guarantee in value; 74 were within 10% f the value guaranteed and 7 were 10% or more below the guaranteed value. ix of the 922 samples which contained nitrogen showed inferior nitrogen.)f these four were dried manures and one was a tobacco product.

The object of the Indiana Fertilizer Law is to secure correct labeling f the fertilizer offered for sale. It is not the intent of the law to determine hat type of fertilizer may be sold. The law is designed to furnish the urchaser with certain information on the state tag that will enable him to ecide whether or not the fertilizer is the type that will meet his needs. he Indiana state tag gives a statement of the percentages of total nitrogen, tal or available phosphoric acid and water soluble potash. With this inormation available the purchaser should be able to judge whether the ferlizer offered for sale meets his requirements. *In order to do this the conumer must read carefully and understand thoroughly the information on the tate tag.*

The Indiana Fertilizer Law protects the honest and efficient manufacturer, ealer and agent as well as the consumer. Full cooperation on the part of the anufacturer, dealer, agent and consumer is necessary in order to accomplish he full purpose of the law.

A copy of the full text of the law will be sent to persons making requests or the same to the State Chemist, Purdue University Agricultural Experiment tation, Lafayette, Indiana.

REFUNDS

The deficiencies on which refunds in 1931 were based were fairly well istributed among nitrogen, phosphoric acid and potash. Available phosphoric cid deficiencies resulting from the use of anhydrous ammonia should be liminated in future shipments on account of the adoption of the new method* r determination of insoluble phosphoric acid.

Every year a few cases of deficiencies occur due to errors in labeling e fertilizer. This results from carelessness on the part of the person reponsible for attaching the tags. Manufacturers should guard against such rrors.

When deficiencies in analysis amounting to $1.00 or more per ton on aw materials, as calculated from the wholesale price, are found, refunds re calculated and indicated on the report of the analysis which is sent to the manufacturer and to the consumer. Refunds on mixed fertilizers a usually calculated when one ingredient is deficient to the extent of $1.00 more per ton regardless of the excess in amounts of the other ingredient Nitrogen, phosphoric acid and potash play definite roles in crop productio An excess of one ingredient will not necessarily compensate for a deficien of another.

---

* The use of one gram of sample in place of 2 grams and digesting for a period of one ur in place of one half hour.

All refunds are required to be distributed to the consumer wherever po sible and receipts for the same must be filed with the State Chemist. In ca there are no records as to the consumer the refunds may be turned over a local charitable organization but receipts for the same must be filed wi the State Chemist.

The payment of a refund by the manufacturer to the consumer does n remove the violation but it does indicate good intentions on the part of t manufacturer and shows his willingness to do what he can to correct t violation in so far as possible. However the payment of the refund does n nullify anyone in the state to call a deficiency of analysis to the attenti of the Prosecuting Attorney.

Refunds amounting to $493.21 were paid by 20 manufacturers on 62 shi ments of fertilizer in 1931.

MANUFACTURERS

Manufacturers should not ship fertilizer without having it proper labeled with Indiana state tags. Experience has shown that when this done it is difficult to avoid the sale of untagged fertilizer. *Several cases this kind were called to the attention of the Prosecuting Attorney in 19 with the result that the manufacturer paid a fine of $50 and costs.*

The State Chemist has no authority to grant permission to a manufa turer to ship unlabeled fertilizer.

All fertilizer offered or exposed for sale or sold in the state which do not equal the minimum guarantee for each ingredient stated on the offici label is mislabeled. An excess of one ingredient in this case will not co pensate for a deficiency in another.

Before offering or exposing for sale any material used for manuring pu poses except barnyard manure, marl, lime, wood ashes and plaster it must registered with the State Chemist and properly tagged with Indiana sta tags or labels. Each package of 200 pounds or fraction thereof must ha attached to it an Indiana state tag. Bulk shipments must be accompani by labels sufficient to cover the total weight of the material.

AGENTS, DEALERS AND DISTRIBUTORS

Each package of fertilizer offered or exposed for sale or sold in India must have attached to it the Indiana state tag bearing the facsimile signatu of the State Chemist (see reproduction page 13). Any alteration of the I diana state tag constitutes a violation of the law. Two cases of this natu by one manufacturer were called to the attention of the Prosecuting Attorn in 1931.

Make contracts on the basis of the guarantee on the official state lab Since local agents are directly responsible for the fertilizer that they off or sale they should deal only with those manufacturers who agree to assume ll responsibility in cases where the fertilizer fails to meet the requirements f the law.

When inspection reports show that fertilizer in your possession is deficient nough so that a refund is calculated on it, withdraw it from sale at once and otify the State Chemist giving the date and the amount withdrawn from sale.

CONSUMERS

Refuse to accept any fertilizer which does not have the Indiana state tag r label attached to each package showing a guaranteed analysis agreeing vith the guarantee under which it was purchased.

When inspections are desired do not forward samples but notify the State hemist telling how much you have on hand and send in a copy of the official abel which is attached to the fertilizer.

Purchase the type of fertilizer that will meet the plant food requirements f your crops. Consult circular No. 162 of the Purdue University Agricultural xperiment Station entitled "Fertilizer for Indiana Soils and Crops."

Let the formula be your guide rather than the brand name. Study the nnual fertilizer inspection circulars of this department and purchase your ertilizer from those companies whose records of inspection show that they re shipping properly tagged fertilizer which meets the guarantee.

SPECIALS

The Indiana Fertilizer Law is essentially a correct labeling law. A poor ertilizer may be sold under the law provided it is correctly labeled. The resence of the official Indiana tag does not mean that the fertilizer is recomnended by the State Chemist. It merely shows that the manufacturer has omplied with the fertilizer law by registering the material and attaching o it an Indiana state tag on which is shown the manufacturer's guaranteed nalysis.

In order to obtain the full benefit of the law it is necessary for the conumer to read the tag carefully, to consider the information given on the state ag and to be guided by the analysis rather than by the brand name or claims f the agent.

There are now registered and offered for sale in Indiana mixtures of ock phosphate and potash and mixtures of rock phosphate, potash and nitroen salts of which the following are typical examples:

1. Mixtures of rock phosphate and potash in which the guarantees are 19.0% total phosphoric acid and 19.0% water soluble potash or 24.0% total phosphoric acid and 12.0% water soluble potash.
2. Mixtures of rock phosphate, potash and nitrogen salts in which the guarantees are as follows: 2.0% total nitrogen, 24.0% total phosphoric acid and 6.0% water soluble potash or 4.0% total nitrogen, 22.0% total phosphoric acid and 6.0% water soluble potash.

These mixtures have been referred to in unfair trade practices as 0-19-19, -24-12, 2-24-6 and 4-22-6. The consumer should keep in mind the difference etween total and available phosphoric acid. A fertilizer of the grade 0-24-12 recognized as containing 24% available phosphoric acid. These mixtures made from rock phosphate contain much smaller amounts of available phosphoric acid. The value of the total phosphoric acid in one of these mixtures is 30 cents per unit while that of available phosphoric acid is $1.00 per unit.

Different fertilizers may be satisfactorily evaluated by calculating the value of the ingredients of each one according to the same standard. Using $1.50 per unit for nitrogen, $1.00 per unit for potash, $1.00 per unit for available phosphoric acid and $0.30 per unit for insoluble phosphoric acid which has about the same value as the total phosphoric acid in raw rock phosphate we find that a rock phosphate mixture containing 2.0% nitrogen, 24.0% total P_2O_5 and 6.0% water soluble potash has a value of $16.20 while a regular 2-24-6 has a value of $33.00 per ton. The method of calculation is as follows:

FOR ROCK PHOSPHATE MIXTURE

2 units of nitrogen	$3.00
24 units of total P_2O_5 from rock phosphate	7.20
6 units of water soluble potash	6.00
Total	$16.20

FOR THE REGULAR 2-24-6

2 units of nitrogen	$3.00
24 units of available P_2O_5	24.00
6 units of water soluble potash	6.00
Total	$33.00

In the group of comparisons that follow the above values were applied to the different analyses and this value was then inserted between the high and low retail price as found on the open Indiana fertilizer market in 1931.

Analysis	Minimum Retail Price	Comparative Value	Maximum Retail Price
2–12–6	$24.85	$21.00	$38.00
4–24–12	47.55	42.00	68.05
2–16–8	28.00	27.00	43.15
1–8–4	23.00	13.50	25.75
2–12–2	21.00	17.00	33.15
4–24–4	37.00	34.00	57.50
4–16–4	38.00	26.00	45.30
2–16–2	30.00	21.00	32.00
*"2–8–8–6"	35.00	19.40	35.00
*"0–6–6–10"	36.60	16.00	36.60
0–14–6	23.30	20.00	28.35
0–28–12	61.35	40.00	61.35
0–12–12	26.25	24.00	36.95
0–24–24	62.95	48.00	65.00
0–10–10	23.30	20.00	32.00
0–20–20	44.07	40.00	57.10
3–18–9	35.50	31.50	46.95
3–9–18	32.00	31.50	46.90
†1–30 Bone	17.50	22.50	40.00

* The above so-called "2-8-8-6" and "0-6-6-10" are no longer received for registration as such.
†The total phosphoric acid in bone is valued at $0.70 per unit.

MEANING OF ANALYSIS

As recognized under the Indiana Fertilizer Law there are only three valuable fertilizer elements, nitrogen, phosphorus and potassium. These three elements do not occur in a free state but are always combined as chemical compounds. This facilitates the handling of them in commercial fertilizer mixtures. A brief discussion of these, their value and availability as plant food, is given in the following paragraphs.

Nitrogen.

In 1881 when the Indiana Fertilizer Law was passed the principal source of nitrogen was of an organic nature. The nitrogen was derived largely from such products as dried blood, bone, tankage and slaughter house by-products, garbage, tankage, cottonseed meal, castor pomace, tobacco stems, manure sweepings and dried peat. Although there was little water soluble nitrogen in the above products all carry a good source of nitrogen with the exception of garbage tankage, manure sweepings, tobacco stems and dried peat. Since 1881 most of the animal products have been diverted into the mixed feed channels and water soluble forms of nitrogen have taken their place in fertilizer mixtures. Today we find that most of the nitrogen carrying fertilizers have better than 80% of their nitrogen content in some water soluble form.

A few of the sources of water soluble forms of nitrogen are as follows: nitrate of soda (natural and synthetic), ammonium sulphate, cal-urea, cal-nitro, urea and calcium nitrate.

Since water soluble forms of nitrogen are considered as being readily available for plant growth, we class a fertilizer that has 60% of its guaranteed nitrogen as water soluble as satisfactory.

If less than 60% of its guaranteed nitrogen is water soluble then the availability of the insoluble organic nitrogen is determined by the alkaline permanganate method. In this case if the active water insoluble nitrogen is equal to or greater than the inactive the nitrogen is classed as satisfactory. If less than half of the insoluble nitrogen is active the nitrogen is classed as inferior.

Manures and garbage tankages that have not been acidulated show an inferior quality of nitrogen. This is not the fault of the manufacturer when they are sold as manure and garbage tankage.

The past year's inspection had six samples showing an inferior source of nitrogen, of which number, four were dried manures and one a tobacco product. This is noted and set forth in Table 11 of this Circular.

Phosphoric Acid.

The phosphorus in the fertilizer is linked up as chemical compounds with calcium, iron and aluminum. It may be as mono-, di- or tricalcium phosphate.

As monocalcium phosphate $CaH_4(PO_4)_2$ it is water soluble and readily available to plants for growth.

As dicalcium phosphate $Ca_2H_2(PO_4)_2$ it is water soluble in the soil solution and rendered available to plants for growth.

As tricalcium phosphate $Ca_3(PO_4)_2$ it is somewhat less available to plants.

As a complex tricalcium phosphate combined with fluorine and lime (raw rock phosphate) it is much less available to plants and becomes available only slowly in the soil.

The bulk of the fertilizer sold today contains mixtures of large amounts of mono and dicalcium phosphate and some tricalcium phosphate. This is in contrast to the earlier years when most of the fertilizer used was bone where the phosphorus is present as tricalcium phosphate.

In acidulated goods the phosphorus is sold only on the basis of the available phosphoric acid (P_2O_5) content. The available is the sum of the soluble and reverted phosphoric acid (P_2O_5).

In bone and rock phosphate the phosphorus is sold only on the basis of the total phosphoric acid (P_2O_5) content. It is only fair to state, however, that about ⅓ of the total phosphoric acid (P_2O_5) content of bone is available by the neutral ammonium citrate method while only from two to four per cent of the total phosphoric acid (P_2O_5) of rock phosphate is available by the same method.

Potash.

Potash, as the official label states, must be soluble in water, in which form it is considered directly available for plant use.

No difference in crop growth has been noted in American, French or German potash. Muriate of potash (KCl) being the cheapest has largely supplanted other potash salts for general crops.

CLASSIFIED FERTILIZER SALES

In the early years of the fertilizer business in Indiana the fertilizer consisted almost entirely of bone and animal products. Recently these products have been diverted largely into the feed channels and replaced by superphosphates and nitrogen salts. Additions of potash salts to the superphosphate and nitrogen salts mixtures and various combinations of these ingredients have replaced almost entirely the tonnages that were formerly sold under the general classification of animal by-products. On account of the depressed price of these animal by-products in 1931 there was an increase in the amount of bone meal sold.

Table 1 illustrates the changes that have occurred since the Indiana Fertilizer Law was passed in 1881.

TABLE 1. Classified Fertilizer Sales Since 1883

Year	Total Tons	Tons Nitrogen Salts	Tons Potash Salts	Tons Super-Phosphate	Tons Bone	Tons Raw Rock Phosphate	Tons Phosphate Rock	Tons Ammoniated Super-Phosphate	Tons Complete

* Largely Nitrate of Soda.
† Nitrate of Soda and Ammonium Sulphate.
‡ Light Sales.

MANY GRADES UNNECESSARY

Table 2 shows the tonnage sold under the different grades of analyses. It will be noted that over 80 per cent of the total tonnage was confined to 33 grades while less than 20 per cent or the remaining tonnage was divided among 167 different grades. Considerable saving could be made if the number of grades were materially reduced. At least 75 per cent of these grades could be eliminated without seriously affecting the total tonnage.

TABLE 2. Showing tons sold under 33 analyses for past eight years—calculated from tag sales. A glance at the last two columns shows the difference in tons calculated by tag sales and that reported by Manufacturers as being sold under these 33 analyses for 1931.

ANALYSIS	Year 1924	Year 1925	Year 1926	Year 1927	Year 1928	Year 1929	Year 1930	Year 1931	Rept. by Mfrs. Year 1931

D. Bone Products (Steam and Raw Bone—Fertilizer Tankages)—2,345.2
E. Miscellaneous—2,622.5.

Summary—
1. Total tons reported—184,840.9.
2. Tag sales from firms not reporting—3,655.0.
3. Total tonnage based on reports (Items 1 and 2)—188,495.9.
4. Total tonnage from tag sales—170,777.

EXPLANATION OF TABLES

Buyers of fertilizer for the Fall of 1932 and the Spring of 1933 should read this circular before buying.

A brief study of the column headings will aid in a better understanding of the various tables appearing in this circular.

In case of deficient samples manufacturers were given ten days' advance notice and opportunity to secure a portion of our sample for review of our results by their chemists.

Table 4 sets forth the total tonnage, retail value, cost per ton, pounds of actual plant food per ton and the cost per pound of plant food for the past 12 years.

TABLE 4

YEAR	Tonnage Per Year	Retail Value Dollars	Cost per Ton Dollars	Pounds per Ton Actual Plant Food	Cost per Pound Plant Food Cents
1920	231,791	8,637,055	37.26	328	0.114
1921	187,923	6,031,305	32.10	354	0.091
1922	209,310	5,730,536	27.40	372	0.074
1923	198,581	6,293,033	31.70	412	0.077
1924	192,417	6,479,605	33.68	446	0.075
1925	226,148	8,253,670	36.50	458	0.079
1926	228,280	8,464,607	37.22	452	0.082

1931	170,777	5,503,088	32.22	490	0.065

Since 1920 there has been a gradual falling off in sales of low and medium grade mixed fertilizers while that of high grade fertilizers has maintained a high level.

The comparison of mixed fertilizer sales for the past 12 years follows:

TABLE 5

Mixed Fertilizer	1920 Tons	1921 Tons	1922 Tons	1923 Tons	1924 Tons	1925 Tons	1926 Tons	1927 Tons	1928 Tons	1929 Tons	1930 Tons	1931 Tons
Low and Medium Grade..	84,760	55,887	43,459	25,773	21,759	17,989	16,892	13,722	6,562	10,506	5,001	2,956
High Grade....	57,881	59,809	89,527	104,990	98,832	127,928	146,177	179,695	179,597	248,566	192,792	131,512

Table 6 shows the comparison of tonnages sold for the past twelve years with the amount of actual plant food in tons per year and with the retail value per year. Values were calculated from tag sales and inspection slips.

TABLE 6

Year	Tons Reported by Manufacturer	Fertilizer Tons	Tons of Nitrogen, Phosphoric Acid and Potash	Cost Indiana Farmers

No. 10500

JOHN DOE & COMPANY

of Lafayette, Ind.,

Guarantee this

Doe's High Grade Fertilizer

to contain not less than

4.0 per cent. of total nitrogen, (N).

24.0 per cent. of soluble and reverted phosphoric acid, (P_2O_5).

2.0 per cent. of insoluble phosphoric acid, (P_2O_5).

12.0 per cent. of potash (K_2O), soluble in water.

[The above is the manufacturers or dealers guarantee.]

HRKraybill

State Chemist

Purdue University Agricultural
Experiment Station, Lafayette, Ind.

LABELS

The only label recognized under the law is that bearing the facsimile signature of the State Chemist. (See reproduction). The label as issued is always printed and contains all the facts required by law; any alteration thereon constitutes a violation of the law.

Label No. 10500 guarantees that each 100 pounds of fertilizer will contain at least 4.0 pounds of total nitrogen (N), 24.0 pounds of soluble and reverted phosphoric acid (P_2O_5), and 2.0 pounds of insoluble phosphoric acid (P_2O_5), and 12.0 pounds of water soluble potash (K_2O).

We hope that it will not again be necessary to file affidavits against agents for distributing unlabeled fertilizer. There can be no excuse for shipping unlabeled fertilizer. Agents receiving same should protect themselves by refusing to accept the car. Wire the manufacturer for official labels and write the State Chemist fully concerning the unlabeled shipment.

TABLE 9. Fertilizer Tonnage and Estimated Retail Value, 1931

Class of Fertilizer	Spring 1931 tons	Fall 1931 tons	Total 1931 tons	Estimated 1931 Retail Value Dollars
1. Acid phosphate, 14% and less	281	438	719	$16,163.12
2. Acid phosphate, 16%	1,311	4,469	5,780	114,767.80

Total	118,845	51,277	170,777	$5,503,088.79

* Tonnage in these classes estimated on the 200-pound sack or 10 per ton. All other classes estimated on the 125-pound sack or 16 per ton.

(A) Mixture of rock phosphate, nitrogen, and potash salts.

(B) Mixture of rock phosphate and potash salts.

PRICES USED IN SECURING COMPARATIVE VALUE OF FERTILIZERS

These values are not for the purpose of fixing the commercial value of mixed fertilizers, but are for comparative purposes only. They are for use in comparing the value of inspection samples with manufacturers' guarantees, and can be used advantageously by fertilizer purchasers in calculating the relative values of various brands offered for sale by different manufacturers.

For use in determining the comparative values of fertilizer inspected in 1932 the following prices have been adopted:

	Per lb. cts.	Per unit or per cent, $
All fertilizers		
Nitrogen (N)	7.5	1.50
Potash (K_2O) Soluble in water	5.0	1.00
Soluble and reverted phosphoric acid (P_2O_5)	5.0	1.00
Mixed fertilizers containing nitrogen		
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Precipitated bone		
Available phosphoric acid (P_2O_5)	5.0	1.00
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Animal by-products, bone, tankage, etc.		
Total phosphoric acid (P_2O_5)	3.5	0.70
Basic slag		
Total phosphoric acid (P_2O_5)	4.5	0.90
Rock phosphate (floats) and low grade slag		
Total phosphoric acid (P_2O_5)	1.5	0.30
Mixed fertilizer, acid phosphate, etc., containing no nitrogen		
Insoluble phosphoric acid	.0	0.00

TABLE 10. Summary of Inspection on the Basis of Composition, Guaranteed, Found, and Retail Values

UNIVERSITY OF ARIZONA
LIBRARY

Circular No. 191 June, 1932

REPORT OF MOSES FELL ANNEX FARM

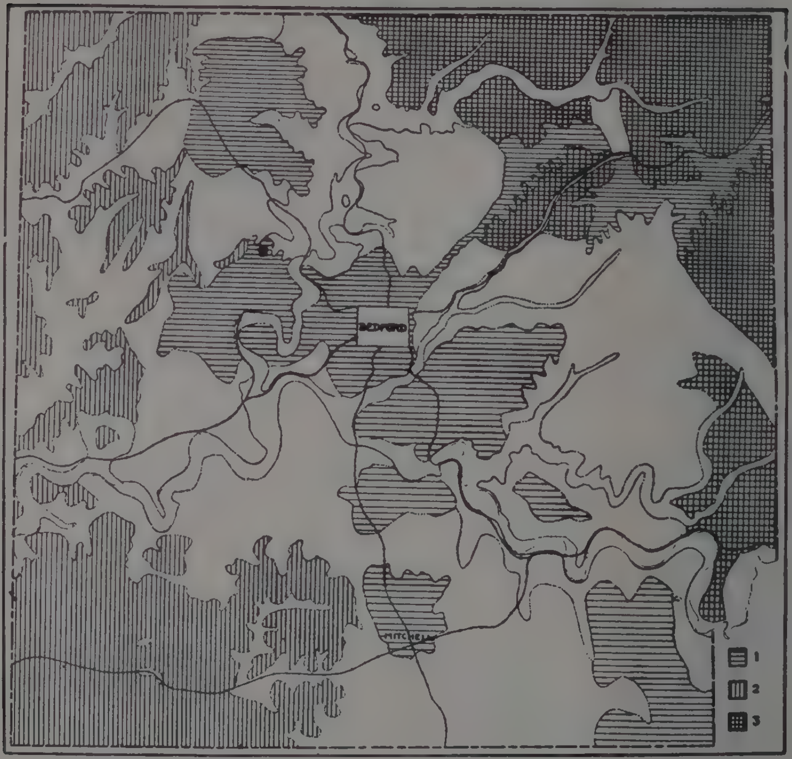
BEDFORD, INDIANA

JUNE 1932

UNIVERSITY OF ARIZONA LIBRARY

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

Map Showing Soil Types Similar to Experiment Field



Region	Principal Soil Characteristics
No. 1.	Yellowish limestone land like Bedford experimental field.
No. 2.	Yellowish "freestone" land.
No. 3.	Like No. 1 on ridge tops and like No. 2 on lower slopes.

The results of the Moses Fell Annex Farm can be applied to the greater part of Lawrence County and surrounding territory.

The soil survey made in this county in 1922 enabled the Department of Agronomy to classify the soils of this section and to indicate the types which can benefit most from the experimental work on this farm.

The results will apply to all similar land in the county, which is indicated by shading No. 1 on the map. They will also apply fully as well to the areas indicated by shading No. 2, and more or less fully to the areas indicated by shading No. 3 where the hilltops are like No. 1 and the lower slopes like No. 2.

Portions of the unshaded area would doubtless respond to similar treatments, but most of it does not need either lime or fertilizer to the same extent as the shaded areas.

Circular No. 191 June, 1932

REPORT OF MOSES FELL ANNEX FARM

June, 1932

H. J. Reed, Farm Director H. G. Hall, Superintendent

The object of the experimental and demonstration work on this farm is to determine the most profitable methods of crop production and utilization, and to adapt and demonstrate new truths and practices that can contribute to a more sufficient, profitable, permanent and satisfying agriculture in southern Indiana.

The farm is a large laboratory where many problems of production are tried in the crucibles of science and practice to get results that would be impossible without such facilities.

Numerous groups of interested farmers visit the experiment plots on this farm each year. The results from this work indicate the most profitable use of fertilizer for crops in this area.

It is important that the farmer shall know definitely what gives the best average returns over a long period of years. The most profitable results come from a system of farming that gives the best average returns. The weather conditions are different each year and these variations in moisture and temperature influence the yields that are obtained.

The soils and crops work carried out under the direction of the Department of Agronomy has been under way since 1915 and clearly demonstrates the value of various applications of plant food and the importance of choosing the best varieties for economical crop production.

The investigations being conducted under the Horticultural Department have demonstrated orchard renovation practice, the value and effectiveness of various spray schedules, orchard fertilization, cool storage management and costs, orchard sanitation, removal of arsenical residue from fruit, adaptation of peach and plum varieties, farm garden and many other phases of horticulture that have added to the knowledge of fruit production. The Entomology Department has rendered valuable service in combatting orchard insects and timing orchard sprays. The Agricultural Engineering Department has studied the use of electricity on the farm, both in the home and on the farm. The Department of Poultry Husbandry has assisted in developing an outstanding flock of Barred Plymouth Rock chickens which has not only contributed information on flock improvement but has demonstrated good housing, brooding methods, feeding and flock management.

The Department of Animal Husbandry is cooperating in a lamb production demonstration that is of interest to sheepmen. A cooperative project is under way to study the milking and beefing qualities of an imported strain of Scotch shorthorn cattle. This work will continue for a long period of years and will yield information on breeding practices that will be of value to breeders of both beef and dairy cattle. Pasture improvement is a matter of economic importance in southern Indiana. The work on this farm is showing that it is possible to improve the carrying capacity of the pasture land and in time a more complete project will be undertaken to coordinate the livestock and pasture work.

The Moses Fell Annex farm serves the farmers of southern Indiana in a very practical way at no cost to the taxpayers of the State. The Hon. Moses F. Dunn and Antoinette Fell gave the farm for this purpose and generously provided for its development so that a long-time constructive effort could be made to develop an agriculture that would improve the land, yield a profit and enrich the state.

GENERAL SOIL FERTILITY TEST

The soil fertility experiments carried on under the direction of A. T. Wiancko, Chief, and G. P. Walker, Associate, of the Agronomy Department are showing striking results that are of great value to the farmers of southern Indiana.

It will be noted, in comparing earlier reports and in examining the crops on the experiment field, that the spread between the good and poor treatments is becoming greater year by year, and that the better treatments are becoming more and more profitable. Without soil treatment, the average value of the crops per rotation of corn, soybeans, wheat, and clover is now $27.80 per acre. With lime, manure and phosphate, the value is $74.95, at an average cost of $7.12 for lime and sulphate.

The largest returns have been secured on the limed land, which has received an average of 6.8 tons of manure for corn and 450 pounds of fertilizer divided between the corn and wheat in the rotation of corn, soybeans, wheat and clover. (Plot 20.) The crop increases from this treatment have averaged $47.65 per acre per rotation as compared with the untreated land (plot 14), or a total of $178.70 in fourteen years. The cost of treatment outside of the manure, which was produced on the farm, has been $17.50 for three tons of ground limestone in 1917, two tons in 1931, and $4.32 every four years for fertilizer, or a total of $33.80 in the fourteen years.

Phosphorus is by far the most important plant food need of this soil. Applications of superphosphate have been highly profitable, either alone or in addition to manure. Without manure (plot 2) 225 pounds of 16 per cent superphosphate for corn and wheat in the four-year rotation has produced average crop increases of 16.5 bushels of corn, 6.3 bushels of soybeans, 8.0 bushels of wheat and 1,083 pounds of hay per acre, valued at $28.05 at a cost of $4.32 for the fertilizer. On land receiving an average of 6.8 tons of manure for corn, a similar use of superphosphate has further increased the crop yields by 9.9 bushels of corn, 6.2 bushels of soybeans, 7.5 bushels of wheat and 1,194 pounds of hay, worth $25.17 at a cost of $4.32 for the phosphate, showing that manure is not sufficient on this land. (Compare plots 16 and 18.)

Manure applied at an average rate of 5.2 tons per acre for the corn has produced average crop increases of 15.7 bushels of corn, 2.2 bushels of soybeans, 2.5 bushels of wheat and 434 pounds of mixed hay per acre, valued at $15.29, which amounts to an average return of $2.94 per ton of manure applied. (Compare plots 14 and 15.)

Ground limestone applied at the rate of three tons per acre in 1917 has so far produced average crop increases of 4.0 bushels of corn, 1.5 bushels of soybeans, 1.6 bushels of wheat, and 492 pounds of mixed hay per acre, valued at $28.14, up to the present time. (Compare plots 13 and 14.)

Lime and manure together have produced average increases of 20.4 bushels of corn, 4.0 bushels of soybeans, 3.7 bushels of wheat, and 739 pounds of mixed hay per acre, amounting to $22.48 for the rotation. (Compare plots 14 and 16.)

Applications of 300 pounds of 0-12-4 on corn and 300 pounds of 4-12-4 fertilizer on the wheat have produced average increases of 18.9 bushels of corn, 5.7 bushels of soybeans, 10.2 bushels of wheat, and 1,067 pounds of mixed hay per acre, amounting to $30.48 at a total cost of $7.38 for the fertilizer. (Compare plots 12 and 14.) The bulk of the increase, however, has been due to the phosphorus in the fertilizer, as is shown in the comparison of plots 2 and 8 with plots 3, 4, 6 and 7.

The field was laid out and tile drained in the spring of 1917. The original rotation was corn, wheat, clover and timothy, but this was changed in 1923 to corn, soybeans, wheat and clover, which is a more suitable rotation for this kind of land. All crops are removed except on plots 6, 7, 8, 10 and 11, where only the ear corn, wheat grain, soybean grain, and clover hay are removed, leaving all the roughage except the clover hay on the land in lieu of manure.

The treatments shown in the second column of the table are as follows: L = ground limestone; Res. = crop residue; O = no treatment; M = manure.

All limed plots received 3 tons of ground limestone per acre in the spring of 1917 and an additional 2 tons in 1931. The fertilizers indicated in the table have been applied at the rate of 200 pounds per acre in the row for corn and 400 pounds for wheat since 1929. To the end of 1928 the potash in the fertilizer was 4 per cent and the phosphorus and potash were equally divided between the corn and wheat, but the nitrogen was all applied for wheat, half in the fall and half in the spring.

The manure applications consisted of 6 tons per acre plowed under for corn in the first round of the rotation. Since then the rate of manuring has been equal to the amount of produce removed during the previous round of the rotation except the wheat grain.

The following table shows the results of different soil treatments begun in 1917:

RESULTS OF GENERAL FERTILITY TEST

Average Yields Per Acre and Financial Statement Per Rotation[1]

[1] The crop rotation was changed in 1923 from corn, wheat, clover and timothy to corn, soybeans, wheat, clover.
[2] Value of grain and hay increase due to residues alone.
[3] Value of increase, cost and net for liming to date.
[4] Value of increase due to manure used alone.
[5] Value of increase per ton of manure.
[6] Value of increase due to manure over lime.

NOTE.—In computing the financial results, corn has been valued at 50c, wheat at 75c and soybeans at $1.00 per bushel; stover at $2.50, wheat straw at $2.00, soybean straw at $3.00 and hay at $10.00 per ton. Nitrogen has been charged at 7½c, phosphoric acid at 6c and potash at 6c per pound. Ground limestone has been charged at $3.50 per ton.

These crop prices are based on the average Dec. 1st Indiana prices of the last three years (1929, 1930, 1931) but reduced to convenient round numbers. The actual averages were: corn, 54c; wheat, 76c; soybeans, $1.03; hay, $10.50. The fertilizer prices used are the 1932 spring cash prices.

Comparison of Different Phosphates

The object of this experiment is to determine the relative values of superphosphate, rock phosphate, bone meal, and basic slag as phosphatic fertilizers. Superphosphate and rock phosphate are also compared in several different proportions with and without lime, manure, nitrogen and potash fertilizers. The table following shows the results to date of treatments begun in 1916.

The largest returns have been secured from the combination of ground limestone, manure and medium to heavy applications of superphosphate (plots 5 and 26). The heavy treatment (plot 26) has produced average increases of 26.8 bushels of corn, 10.7 bushels of wheat, and 1,603 pounds of mixed hay per acre, valued at $39.64 per rotation or a total of about $211.51 per acre since 1916, when the treatments were begun, at a total cost of $44.05 for lime and phosphate. Twenty-one dollars of this cost was charged for 4 tons of limestone, applied when the experiment was begun, and 2 tons applied in 1931. (Compare plot 26 with 33.)

In combination with lime and manure, superphosphate has been the most profitable source of phosphorus, the returns per acre per rotation, above the cost of materials, from the lime and different phosphates averaging as follows: superphosphate, $14.77; basic slag, $13.77; steamed bone meal, $11.78; and rock phosphate, $10.48. (Compare plots 5, 3, 2 and 6.) In this comparison, superphosphate, basic slag and steamed bone meal have been applied at the rate of 48 pounds and rock phosphate at 192 pounds of phosphoric acid per acre with manure for each corn crop.

On limed land, superphosphate has been more efficient than rock phosphate in all cases, whether used in large or small amounts, and with or without manure or nitrogen and potash (compare plots 5, 11, 17, 23, 26 and 29 with plots 6, 12, 18, 24, 27 and 30).

On manured land without lime, rock phosphate has been slightly more profitable than superphosphate (compare plots 8 and 9).

Without manure, rock phosphate alone has produced larger returns than the combination of lime and superphosphate. In both cases the crop yields have been too low to be profitable.

This field was laid out and tile drained in the summer of 1915. The crop rotation is corn, wheat, and clover with all produce removed except second growth clover.

The treatments shown in the second column of the table are as follows: L = ground limestone; M = manure; St. B. = steamed bone meal; BS = basic slag; SP = superphosphate; RP = rock phosphate; N = 12 pounds nitrogen; K = 50 pounds potash.

Ground limestone was applied at the rate of 4 tons per acre in 1915 and an additional 2 tons in 1931.

Manure was applied at the rate of 6 tons per acre for corn in the first round of the rotation and since then in amounts equal to the produce removed except wheat grain. The phosphates are applied at the rates shown in the third column in the accompanying table. The rock phosphate is plowed under for corn and the other phosphates, and the nitrogen and potash, are broadcast and harrowed in before planting.

RESULTS OF PHOSPHATE EXPERIMENT

Average Yields Per Acre and Financial Statement Per Rotation

(Plots 17, 18, 20 and 21 received 12 pounds of nitrogen and 50 pounds of potash per acre per rotation, all on the corn.)

[1] Value of increase due to lime over manure.

[2] Value of increase due to manure.

[3] Value of increase per ton of manure.

[4] Value of increase due to lime and manure.

[5] Manured on Series B in 1916 and Series C in 1917.

[6] Applied in 1916 and again in 1925.

[7] Total value of increase, cost, and net returns to date.

NOTE.—In computing the financial results, corn has been valued at 50c and wheat at 75c per bushel; stover at $2.50 wheat straw at $2.00, and hay at $10.00 per ton. Nitrogen has been charged at 7½c, phosphoric acid at 6c and potash at 6c per pound. Rock phosphate (30%) has been charged at $15.00, and ground limestone at $3.50 per ton.

These crop prices are based on the average Dec. 1st Indiana prices of the last three years (1929, 1930, 1931) but reduced to convenient round numbers. The actual averages were: corn, 54c; wheat, 76c; soybeans, $1.03; hay, $10.50. The fertilizer prices used are the 1932 spring cash prices.

Variety Tests of Farm Crops

The selection of hardy, high-yielding varieties of the crops grown in any section is very important. To determine those best adapted for this part of the state, the most promising varieties of several crops have been compared each year for a number of years. Each variety has been harvested separately and the yields determined by weight. The land on which the variety tests are carried has been kept in a good state of fertility by uniform applications of fertilizer on wheat, and manure on each corn crop.

Pasture Experiments

The improvement of pasture land has a very definite place in the agricultural program for southern Indiana. Large areas of this section are better adapted to pasture purposes than to its present use. There is a considerable area of pasture land that is not producing in a satisfactory way. The development of better pastures will make possible the expansion of the livestock industry from both the beef cattle and the dairy cattle point of view.

Several years ago a series of pasture plots was laid out in one section of the old pasture, and the results of soil treatments are given in the following table.

Grass mixtures including timothy, red top, Kentucky blue grass, orchard grass, alsike clover, sweet clover, alfalfa and lespedeza were seeded on the plots in April, 1924. The first 2 years' growth was largely alsike clover, timothy and red top with scattered clumps of orchard grass, sweet clover and alfalfa.

After 8 years blue grass and red top persist along with some timothy on the fertilized plots. Blue grass is much better on the limed and phosphated areas than on the unlimed. Most of the lespedeza, both Korean and common, seems to have disappeared in the extreme drouth of 1930. Hop clover, a member of the clover family, gradually came into the mixtures. This early growing legume seems to have some real worth for rolling pasture land of this type.

For new pasture seedings a mixture of timothy, red top, blue grass, alsike clover and common lespedeza is recommended for rolling limestone land. On sour thin land, a mixture of lespedeza and red top seems best.

*Treatments applied at seeding time in April, 1923, and fertilizer repeated in fall of 1929. Plots 2 and 9 receive top dressings of 100 pounds of nitrate of soda per acre each spring.

All this experimental work, including some crop rotation experiments and the test of nitrogen top dressing of wheat will be seen on the fields.

HORTICULTURAL WORK

The Horticultural Department, Professor L. Greene, Chief and Professor C. L. Burkholder, Assistant Chief, is carrying on numerous projects of interest to fruit growers of the State.

Most of the apple trees in the present planting were set when the farm was given to the University by Mr. Dunn. A few blocks of young trees have been planted and as the old trees die out replants have been put in. The replants have been grown by means of a heavy straw mulch around each tree.

At present there are about 80 acres of apples, 3 acres of plums and prunes, 4 acres of peaches and 1 acre of plums on the farm.

Peach Plantings

The peach orchard is on the south side of the orchard. The first 17 rows are Elberta and are now 15 years old. In the spring of 1932 practically all the fruit buds were killed and the trees have been heavily cut back. The south side of the orchard was not cut back until the week of May 22.

The peach trees were cut back severely after it was evident that the crop had been lost. New wood will be produced for a crop next season.

The Rochester and Champion still have a prospect for a light crop and have not been cut back. Four year old South Haven also came through the adverse weather conditions very nicely for a time but finally dropped nearly all of their fruit.

Plum and Prune Orchard

About 25 varieties are being tested. Most of the trees are four years old. The cold temperatures of early March killed fruit buds and injured the trees of several varieties and these have been removed and replaced with other more promising sorts. This spring a number of the varieties had considerable bloom and set some fruit. Among these are Hall, Robert's Prune, President, French Damson, Stanley and Pacific. These varieties not only show an early bearing tendency but came through the March freeze and spring frosts without injury. Where fruit growers are interested in local sales, good canning varieties of plums will prove popular as well as furnishing a very welcome income many years when peaches are a failure.

Pears

The planting of pears is for the purpose of trying out some of the new blight resistant varieties along with new methods of blight control by means of spraying and the use of resistant stocks.

Portable vs. Stationary Spraying

In 1930 about 45 acres of the apple orchard was equipped for stationary spraying. The 35 acre block on the south side of the orchard is still being sprayed with the best portable equipment. So far very little difference has been noted in insect and disease control between these two blocks. In 1931 there was some evidence of a heavier codling moth infestation in the stationary sprayed area.

Some idea of the speed and cost of spraying these two areas may be had from the following figures. On the average the cost of spray application per 1,000 gallons has been about twice as much on the portable block as compared to the stationary method of spraying. The saving in labor and power on the pink and calyx sprays in 1932 has amounted to $55.93.

Comparison of Cost of Pink and Calyx Spray Application in Portable and Stationary Blocks, 1932.

Pink Spray—Portable Block

No. gallons spray applied	5550
Labor, 3 men for 29 hours at 25c	21.75
Tractor rental at 75c per hour	21.75
Oil and gas for sprayer engine	1.80
Total cost, labor and power	45.30
Cost of application per 1000 gallons	$8.20

Pink Spray—Stationary Block

Total gallons spray applied	4050
Labor, 13 hours for 4 men at 25c	13.00
73 K.W.H. of electricity at 5c	3.65
Total cost of labor and power	16.65
Cost per 1000 gallons spray applied	$4.06

Calyx Spray—Portable Block

No. gallons spray applied	6750
Labor, 3 men, 28 hours at 25c	21.75
Tractor rental, 28 hours at 75c	21.75
Gas and oil for sprayer engine	2.00
Total cost labor and power	44.00
Cost of application per 1000 gallons	$6.56

Calyx Spray—Stationary Block

No. gallons spray applied	6700
Labor, 12 hours for 4 men at 25c	12.00
52 K.W.H. power at 5c	2.60
Total cost labor and power	14.60
Cost of application per 1000 gallons	$2.16

Icing Experiment in Apple Storage

Experiments in icing a common storage were continued at Moses Fell Annex during the season of 1931-32, using cracked ice and salt in a new type of ice bunker. The season was the warmest on record for many years but a prevailing temperature several degrees lower than that obtained with the type of ice bunker used in previous years was secured. Pressure test records showed that the fruit in the iced room ripened much slower than that in the ventilated room. Grimes and Jonathan in the iced room remained in saleable condition four to six weeks longer than fruit of the same quality and variety in the ventilated room. Because of the extreme heat and long season over which it was necessary to use ice, the cost of this item was higher than in previous years. Based on an average season, however, the cost would likely be less as the cooling capacity of the ice is used more effectively. Where Grimes and Jonathan are being held for local or truck trade fifteen to twenty-five cents per bushel can profitably be invested in some method of supplementing the use of cool air at night. This is especially true during the months of September and October.

Spraying and Residue Experiments

A number of different spray schedules have been tried in the M. F. A. orchard during the past few years. Codling moth have been a serious menace in this area since 1925. The United States tolerance for arsenic has been gradually reduced and new spray combinations have been tried in an effort to obtain satisfactory codling moth control without objectionable residue.

Careful examination is given to the fruit from experiment plots to determine the value of various treatments for disease and insect control.

In 1931 three applications of arsenate of lead combined with a fish oil sticker were used in all of the apple orchard against first brood codling moth. Beginning with the second brood sprays a part of the orchard was sprayed with summer oil and summer oil and nicotine in place of arsenate of lead. Under these conditions the residue was as high on the oil sprayed varieties as on the same varieties given two or three arsenate of lead and lime sprays beginning July 1st.

Apple Washer

An apple washer was installed in 1931 as part of the packing house equipment at M. F. A. Fifteen thousand nine hundred and forty-eight bushels of apples were put through the washer at the rate of 75 to 85 bushels per hour. In 1931 the cost of power as used in the packing shed was only three cents per kilowatt. At that rate the power cost for washing the entire crop averaged 1-20 cent per bushel. The total cost of washing per bushel including 15 per cent of cost of washer was 1.05 cents per bushel. Washed and unwashed samples of each variety were held in storage for observation. No injury from the chemicals used could be detected as late as February 1, 1932.

Tests with Various Washing Materials and Methods of Washing

1. The average arsenical removal secured amounted to 2-3 of the amount of arsenic present before washing.
2. Increasing the strength of acid from 1½ to 3% by volume failed to increase the efficiency of arsenical removal.
3. Cold sodium metasilicate was slightly less efficient than cold 2 or 3 per cent hydrochloric acid (by volume).
4. The addition of an emulsifier to the sodium metasilicate slightly increased its efficiency.
5. A heating plant was installed for the cleaning solution in the washer but the results in 1931 (with hot 2 per cent by volume hydrochloric acid) did not show any increase in the percentage of removal on most varieties and where there was an increase it was very small. There seems to be more promise in some of the newer cleaning materials and methods than there is in using hot cleaning solution. The results in the Pacific Northwest show a definite increase in arsenical removal with hot acid but they have used a much higher strength acid than was used in this work.
6. The average arsenical load on twelve varieties from the M. F. A. orchard in 1931 was .0213 grain per pound before washing and the highest sample .0286. The average arsenical load after washing was .007 grain of arsenious trioxide per pound.

The Department of Entomology has Mr. G. E. Marshall stationed at Bedford to carry on a series of experiments for the control of the codling moth and oriental peach worm. A laboratory for this work is provided on the Moses Fell Annex Farm. Observations are made for the timing of sprays in southern Indiana so that full advantage may be taken by the growers of existing methods of control. New spray materials are being tested out, sanitation methods are practiced and the life history of the orchard pests and their parasites are studied.

Demonstration Farm Garden

During the season of 1931 a farm demonstration garden was laid out on the Moses Fell Farm under the direction of Professor F. C. Gaylord in order to demonstrate the cash value of a real garden, in addition to that of having a ready supply of wholesome fresh vegetables for the entire family. The first garden produced vegetables valued at $109.75 (market value) that were used on the farm. In addition a considerable supply was left. The following recommendations are suggestions and may be changed to meet individual farm needs. The plan outlined was one successfully used on farm garden demonstrations.

Amounts Harvested and Used Only

Cash Value—(Based on Market Prices) $109.75

Radishes	45 doz.	Tomatoes	450 lbs.
Onions	12 doz.—20 lb. dry	Peppers	13 doz.
Kale	6½ lbs.	Cucumbers	65 doz.
Spinach	1½ lbs.	Carrots, 35 doz. bunch	6 doz.
Lettuce	4 lbs.	Parsley	¼ doz.
Turnips	15 lbs.	Cantaloupes	70
Peas	64 lbs.	Eggplant	2
Beets	78 lbs.	Sweet Potatoes	342 doz.
Beans	318 lbs.	Watermelons	13 doz.
Cabbage	80 lbs.	Swiss Chard	3 doz.
Potatoes	23 lbs.	Lima Beans	10 doz.
Salsify	2 lbs.		

Suggestions for Laying Out the Farm Garden

1. Lay out necessary half acre of best adapted garden soil available. This tract to be as near the farm residence as possible.
2. Apply at least ten loads of stable manure (cow manure preferable) on this plot before breaking.
3. Plow as early as ground can be worked. (Soil should be plowed 8 to 10 inches deep if possible.)
4. Thoroughly prepare soil entire depth broken just before planting, then apply broadcast, 500 pounds of 3-18-9, or its equivalent, working it into top three inches of soil.
5. Practice level, shallow cultivation and give good culture throughout the season, to control pests and conserve moisture.
6. Keep records of crops and amounts harvested so you may change plans to meet your own needs.

PLANTS AND SEED REQUIREMENTS

Early Cabbage Plants:	Golden Acre	4 dozen
	Copenhagen Market	4 dozen
Tomato Plants:	Early—Break O'Day	2½ dozen
	Pritchard	2½ dozen
	Late—Indiana Baltimore	2½ dozen
Peppers:	Sweet—Giant or Baltimore	2½ dozen
Eggplant:	Black Beauty	3 dozen
Asparagus:	Washington	12 dozen
Rhubarb:	Victoria	1½ dozen
Sweet Potato Plants:		200

SEED REQUIREMENTS

For Spring and Summer Plantings

Vegetable	**Variety**	**Amount**
Leafy Lettuce	Grand Rapids	½ ounce
Early Radish	Red-Scarlet Globe	½ ounce
	White—White Icicle	½ ounce
Onion Sets	Yellow	4 quarts
E. Turnips	Purple Top Strap Leaf	½ ounce
Peas	Alaska	3 pounds
	Onward	3 pounds
	Thos. Laxton	3 pounds
Parsnips	Hollow Crown	½ ounce
Beets	Early Wonder	1 ounce
	Detroit Dark Red	1 ounce
Onion Seed	Yellow Globe or Valencia	1 ounce
Salsify	Mammoth Sandwich Island	1 ounce
String Beans	Stringless Green Pod	5 pounds
Kale	Dwarf Curled Scotch	½ ounce
Parsley	Extra Double Curled	1 packet
Chard	Lucullus	1 packet
Bush Lima Beans	Henderson Bush Lima	2 pounds
Sweet Corn	Golden Bantam	3 pounds
	Bantam Evergreen	2 pounds
Pole String Beans	Kentucky Wonder	2 pounds
Carrots	Early Scarlet Horn	½ ounce
	Chantenay	½ ounce
Cantaloupe	Honey Rock	2 ounces
	Bender's Surprise	2 ounces
Watermelon	Kleckley Sweet	2 ounces
Cucumbers	Early Fortune	1 ounce
	Snows Pickling	1 ounce
Winter Squash	Table Queen	1 ounce
	Improved Hubbard	1 ounce
Summer Squash	New Jersey White Bush	1 ounce

LIVESTOCK

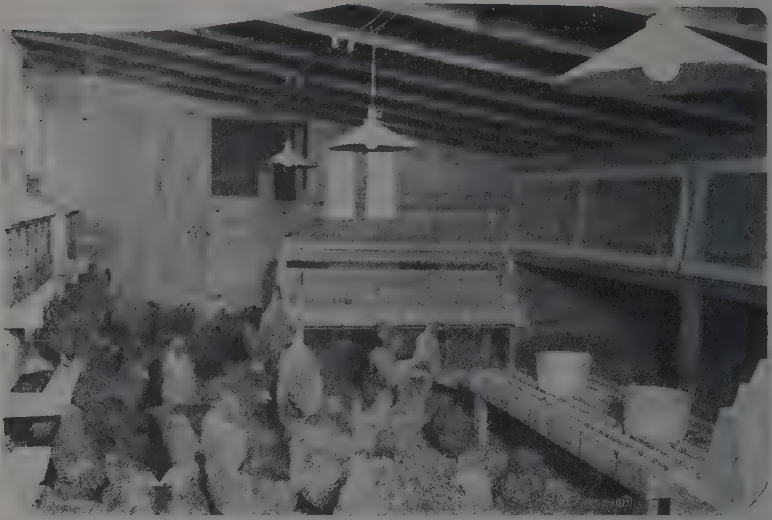
The livestock work on the farm has been continued on the same basis as last year, with the cooperation of Professor F. G. King, Chief, and Professor Claude Harper, Assistant Chief of the Department of Animal Husbandry. The lamb production test has been carried on using a lot of type C merino ewes headed by a merino buck, and the following lots each headed by a southdown buck—merino ewes; western ewes and native ewes. Records are being kept of the feed consumption so that costs, gains, profits and effect on wool production can be determined. The sheepmen of southern Indiana will find much information of value to them in this test. If the farmers of southern Indiana are going to realize the maximum returns from their flocks of sheep it is important that the accurate information should be available regarding the performance of the best adapted breeds of sheep.

The lamb production test compares lambs from merino, native and western ewes. Accurate records are kept of feed used in each lot and the wool produced by each group of ewes.

The herd of young cattle is developing nicely. These animals will be the basis for studying the milking and beefing qualities of this strain of shorthorn cattle. A survey conducted by the United States Department of Agriculture brought out the fact that a majority of the general farmers of the corn belt were interested in a type of cattle that would produce milk for home and steers for the feed lot. This project is carried on in cooperation with the Bureau of Animal Industry, U. S. Department of Agriculture, and it is hoped that much valuable data will be obtained which will be of interest to all cattle breeders. Records and observations will be made regularly on these animals so that the dual qualities of the progeny may be accurately measured.

Poultry

The flock of Plymouth Rock chickens continues to improve. Fifty of last year's pullets completed records satisfying the Record of Performance requirements and the breeding pen for this year was made up entirely of birds that had R. O. P. certificates. The improvement of the flock may be noted in the fact that fifty of the best pullets in the house at this time had an average production of 161 eggs per bird on April 30th.



Good practical equipment is provided for the flock of chickens. A steady improvement has been made in the average production of the flock.

Mr. S. M. Walford of the Department of Poultry Husbandry advises regarding the management of the flock and plans the breeding program for the development of the flock. Some chicks from an outstanding flock have been added this season to provide additional breeding stock for outcrossing.

The flock is blood tested three or four times a year to eliminate and prevent disease.

Tobacco Experiments

The preliminary tests with tobacco have been continued to study the responses of this crop to fertilizer. In contrast with the results of the previous season, plant food had a tremendous effect upon the yield per acre.

Plot No.	Fertilizer per Acre	Yield per acre pounds	Graded as follows			
			Red	Lugs	Trash	Tips
1	1000 lbs. 3-14-5	1796	448	220	880	320
2	500 lbs. 3-14-5	1548	576	92	616	264
3	250 lbs. 3-14-5	1592	624	184	592	192
4	None	840	284	80	340	136
5	500 lbs. 6-15-9	1824	632	216	696	280
6	200 lbs. sulfate of potash	1572	572	320	452	228
7	400 lbs. sulfate of ammonia—2 applications	1584	496	336	472	280
8	500 lbs. 24% phosphate	1736	664	472	400	201

CIRCULAR No. 192 SEPTEMBER, 1932

INSPECTION OF AGRICULTURAL SEEDS

Buckhorn plants, a troublesome perennial, the seeds of which are often found in improperly cleaned clover, timothy and lawn grass seed.

SITY OF A
LIBRARY

Agricultural Experiment Station
Purdue University
Lafayette, Indiana

Reuben Oscar Bitler, Deputy in the State Chemist Department, after twenty-one years of service, died April 22, 1932. The fertilizer, feed and seed industries as well as the agricultural interests of Indiana have suffered a distinct loss through the death of Mr. Bitler.

* * *

This circular is a report of the agricultural seed inspection work for the year ending June 30, 1932. The inspectors visited seed dealers in all sections of the State and collected 1,177 official seed samples. In addition to these 2,628 free test samples of seed were tested during the year.

In accordance with the ruling of the State Seed Commissioner, wholesale seedsmen are required to attach at least one state label to each package of seed delivered to the retail seedsmen, who is then required to attach sufficient additional labels to cover the net weight of the package.

Since it is impossible to test all seed promptly during the rush season directions are given for making germination tests at home.

Shipments of seed seriously misbranded were withdrawn from sale until dealers relabeled such seed correctly.

Proper use of this publication will enable purchasers to discriminate between seedsmen who handle good seed and those who handle poor seed. Before buying seed farmers are urged to examine Table 7 "Summary of Seed Inspection."

Due to lack of funds the table giving the analyses of individual samples is omitted from the report this year. It is the intention to resume publication of this table in future reports as soon as funds are available.

INSPECTION OF AGRICULTURAL SEEDS

H. R. Kraybill, State Seed Commissioner

O. S. Roberts R. O. Bitler[1] P. B. Curtis
Regina B. Schulte* Edith M. Patt Pauline Balbach

The Indiana Seed Law is essentially a correct labeling law. The law does not prevent the sale of poor seed. It merely requires that definite information be placed on the label in order that the purchaser may decide for himself whether he wishes to use good seed or poor seed. In order that the necessary information may be available the law requires that the seed be labeled with official Indiana State Labels showing the minimum percentage of purity and of germination and the maximum number of each of the noxious weed seeds per pound. The purpose of the law is to give the purchaser sufficient information to enable him to buy good seed and also to protect the honest and reliable seed dealer and farmer from the practices of the unscrupulous, dishonest and careless seedsman.

This circular contains the results of the inspection of agricultural seeds for the period from July 1, 1931, to June 30, 1932. The inspectors visited the seed dealers in all sections of the state and collected 1,177 official samples of seed. Complete analyses of these samples were made and reports were sent to the retail dealers as well as to the distributors of the seed. In addition 2,628 free test samples and 39 Custom House samples were analyzed. The testing of these samples entailed the making of 2,784 purity tests, 14,496 germination tests, 26 examinations, and 135 identifications.

RESPONSIBILITIES OF THE WHOLESALE SEEDSMAN

The wholesale seedsman is required to attach at least one Indiana State Label to each package of seed delivered to the retail seedsman.

RESPONSIBILITIES OF THE RETAIL SEEDSMAN

The retail seedsman is required to attach sufficient state labels properly filled out to each package of seed to cover the total weight of the seed before the seed is offered or exposed for sale. These labels can be chosen of such denominations of weight so that they may be removed and attached to a portion of the seed which may be sold from the original package. It should be remembered that every package of seed of one pound or more when sold for seeding purposes must have attached to it sufficient state labels properly filled out to cover the total weight of the package. It should also be remembered that it is just as much a violation of the state law to offer or expose seed for sale for seeding purposes without tagging to full weight as it is to sell the same without tagging.

---

* In cooperation with the Seed Laboratory, Bureau of Plant Industry, U. S. D. A.

[1] Deceased April 22, 1932.

RESPONSIBILITIES OF THE PURCHASER

The purchaser should examine the official label carefully before purchasing seed and ascertain whether the seed is of the quality he desires. He should insist that all seed which he purchases be tagged properly with official state labels. Attention should be paid to the date of germination on the seed tag. If the germination test was made more than six months before, in many cases it will be well to insist upon a more recent germination test. Table 7 gives the standing of the distributors as determined by the 1931 inspection. A study of this table will enable you to determine whether or not the seed which they sold met their guarantee. The seed law is designed to offer you protection but it will not give you that protection unless you make use of the opportunity which the law provides for you.

FARMERS' EXEMPTION

A farmer is exempt from the provisions of the seed law when the seed is grown, sold, and delivered by that farmer on his own premises to the purchaser himself. If, however, the seed is advertised for sale by the public press, circular or catalogue, or if the seed is delivered by a common carrier, the farmer is considered as a vendor and must comply with the provisions of the act. Seed taken to community sales for sale must be labeled in accordance with the law.

FREE TESTING OF SEEDS

During the past year 2,628 samples of seed were tested free of charge for farmers and seedsmen. The privilege of having these tests made is one of much value to the farmer and the smaller seed dealers who do not have facilities for testing seeds. Not all of the tests requested can be made promptly during the busy season from January to March. For that reason it is important that you send your samples in as early as possible, preferably from September to December.

Satisfactory tests may be made of the larger field seeds at home, leaving the laboratory facilities of the Experiment Station available for the grasses and clovers which are more difficult to analyze.

DIRECTIONS FOR MAKING YOUR OWN GERMINATION TESTS

The seed to be germinated should be mixed thoroughly and the required number of seeds (100 seeds of grains and 200 of clovers and other small seeds) counted out just as they come.

The plate germinator is satisfactory and very simple to operate. Place the seeds to be germinated between two thicknesses of folded blotting paper or cloth (heavy grade of muslin or canton flannel). This should be moistened and placed between ordinary tin or porcelain plates and kept in a warm room where the range in temperature is from approximately 85 degrees during the day to 65 degrees at night. Select a place for the test not too near a window, stove or register.

The time required for germination tests differs with different kinds of seed. Under favorable conditions grass and clover seeds begin to sprout in three or four days. Continue your tests ten days or two weeks.

Examine your tests every two days, making a record of the number of seeds that have sprouted. Also keep the blotting paper or cloth sufficiently moist. The number of seeds which germinate out of the 100 seeds will give the percentage of germination.

DIRECTIONS FOR TAKING OF SAMPLES

1. The minimum weight of seed forwarded for test should be approximately:
    - (a) Two ounces (cupful) of grass seed of any kind or of white and alsike clover;
    - (b) Five ounces (cupful) of red and crimson clover, alfalfa, millet, flax or seed of like size;
    - (c) One pound (pint) of cereals or seed of like size.
2. They may be drawn:
    - (a) With seed triers;
    - (b) With long stickers;
    - (c) By hand, taking approximately equal parts of the sample from at least three different places in the sack, including the top and opposite sides as near the bottom as practicable.

3. Samples should be drawn from each bag when there are not more than five bags in the lot, from every fifth bag when there are more than five bags, but never from less than five bags. Each sample so drawn is combined into one composite sample.

TOLERANCE

Under the most perfect and approved conditions of testing seeds variations will occur in purity and germination tests. For this reason the Association of Official Seed Analysts has adopted tolerances or allowances for purity and germination tests. Samples of seed with a guarantee within the tolerances are not considered to be seriously misbranded under the provisions of the Indiana Seed Law, but seed dealers will be expected to change the guarantee on the unsold portions to correspond to the analysis found by the Seed Commissioner.

TABLE OF TOLERANCES FOR GERMINATION TESTS

Percentage of Germination	Percentage of Allowable Variation
90 or over	6
80 or over and less than 90	7
70 or over and less than 80	8
60 or over and less than 70	9
50 or over and less than 60	10
40 or over and less than 50	10
30 or over and less than 40	9
20 or over and less than 30	8
10 or over and less than 20	7
0 or over and less than 10	6

TOLERANCE FOR PURITY TEST

In determining the tolerance for purity the sample shall be considered as being made up of two parts: (1) pure seed and (2) everything not pure seed. The tolerance allowed shall be two-tenths of 1 per cent plus 20 per cent of the lesser part. Example: Seed marked 98 per cent pure, the lesser part is 100 minus 98, or 2. Twenty per cent of 2 equals 0.4. Therefore, the tolerance allowed would be 0.2 plus 0.4, or 0.6.

VIOLATION OF THE LAW

It is a violation of the State Seed Law to offer, expose for sale or sell seed without having it tagged to full weight with official labels or to misbrand the seed. During the past year four cases of non-tagging of seed and nine cases of misbranding were called to the attention of prosecuting attorneys. Of the thirteen cases six resulted in convictions while seven of them have not been reported by the prosecuting attorneys to date.

FILLING OUT OFFICIAL LABEL

Purity

The minimum purity means the percentage of pure seed of the kind and variety given on the official label. Statements of purity, as 97 per cent, including 2 per cent crop seeds, or 95 per cent and 2 per cent crop seeds, will not be permitted. In cases where the seed contains two or more kinds of agricultural seed, each present in excess of 5 per cent, the seed should be labeled with the green colored mixture labels, Style C.

The percentage of purity on the large seeds such as soy beans, corn, wheat, vegetable seeds, etc., must be given on the official label the same as on any other seed.

The filling out of the column "per cent of seed" on the mixture labels can be best explained by an example. For instance, if a mixture is composed of 60 per cent Kentucky Blue Grass with a purity of 80 per cent and 40 per cent of Red Top with a purity of 90 per cent, the per cent of Blue Grass should be given as 48 per cent, obtained by taking 80 per cent of 60. The Red Top should be given as 36 per cent, obtained by taking 90 per cent of 40.

Germination

There still appears to be some misunderstanding as to the method of stating the percentage of germination on the official label. The term minimum germination means the percentage of sprouts obtained in the prescribed time for the test. If the seed contains hard seeds this percentage should be stated after the term "hard seed" on the official label. In no case should the sum of the percentage of sprouts and of hard seeds be given as percentage of minimum germination.

Distributors should not ship seed until the germination test is completed. The statement "In Test" on the official label does not meet the provisions of the seed law. Further, if there is a demand for the seed the dealer may be tempted to sell the seed before he receives a report on the germination, thus placing himself liable to prosecution.

Noxious Weed Seeds

The number per pound of each of the noxious weed seeds present must be listed on the reverse side of the tag irrespective of the number present. The term "trace" is not permissible. The statement of the noxious weed seeds in terms of per cent or in terms of proportion will not be permitted.

Place Where Grown

The official tag must give the name of the state, territory or foreign country where the seed was grown. Terms such as Domestic, U. S. A., Northwestern, and Central States do not meet the requirements of the law, and seed found so labeled will be immediately removed from sale until the tags have been corrected.

CERTIFIED, VERIFIED AND AFFIDAVIT SEED

Certified seed is seed whose purity, germination, and variety is certified to by some state certifying agency or an agency closely associated with some state office or department. The seed is shipped in sealed sacks with a certified seed tag attached. During the growing season the fields are inspected to ascertain trueness to variety of crop, and after the harvest the seed is tested to determine whether it meets the prescribed standards of the certifying agency. In Indiana the Indiana Corn Growers' Association certifies corn, wheat, lespedeza, and soy beans. The other most commonly certified seed found in the state is Grimm Alfalfa.

Verified-Origin seed is seed whose origin is attested to by certain government approved seed dealers. Seed verification service deals with origin only, meaning Place Where Grown, and gives no guarantee as to the variety, purity or viability of the seed. At the present time red clover and alfalfa are the only seeds verified as to origin. Verified seed is tagged with tags bearing the official verification emblem.

Affidavit Grimm is alfalfa seed for which the grower has made affidavit as to its being Grimm Alfalfa. This affidavit seed is not regulated by either State or Federal Government.

BARGAIN SEED

A considerable quantity of unclean, weedy, so-called pasture mixtures of low viability has been shipped into the state by certain mail order seedhouses. By means of extensive advertising in leading farm papers many unsuspecting buyers have been influenced in purchasing these dangerous and, in many cases, worthless lots of seed. These mixtures appear to consist of screenings, tailings, and low grade seed mixed together in order to disguise their real quality. The low price attracts the buyers who forget that good seed is not sold below the prevailing market price and that good seed is the cheapest in the end. Most of these cheap seeds lead to poor stands and infestation of the soil with many troublesome weeds.

SUMMARY OF 1932 INSPECTION

Most of the official samples examined during 1932 met their guarantee very closely. However, examination of Table 4 shows clearly that the quality of much of the seed could be improved by more thorough cleaning.

With the exception of a few the seedsmen are showing an increased interest in a desire to cooperate with the department in the enforcement of the seed law. Table 1 shows that there has been a marked improvement in the correct labeling of seeds in the last three years. In 1925, 36.4 per cent of the samples were seriously misbranded, while in 1932 only 17 per cent were seriously misbranded. Tables 5 and 6 show the percentage of official samples of red clover, alfalfa, sweet clover, alsike clover and timothy having various noxious weed seeds. Compared with 1923 and 1931 there is an increase in the percentage of samples of red clover containing dodder. A lower percentage of the alfalfa samples contained dodder than in 1931 and in 1923.

TABLE 1.—PROGRESS IN SEED INSPECTION

YEAR	Number of Samples Examined	Number Seriously Misbranded	Percent Seriously Misbranded
1925	745	271	36.4
1928	969	289	29.6
1929	1,230	403	32.7
1930	1,044	184	17.6
1931	1,122	201	17.9
1932	926	157	17.0

TABLE 2.—AVERAGE ANALYSIS OF SAMPLES IN 1922 SEED INSPECTION

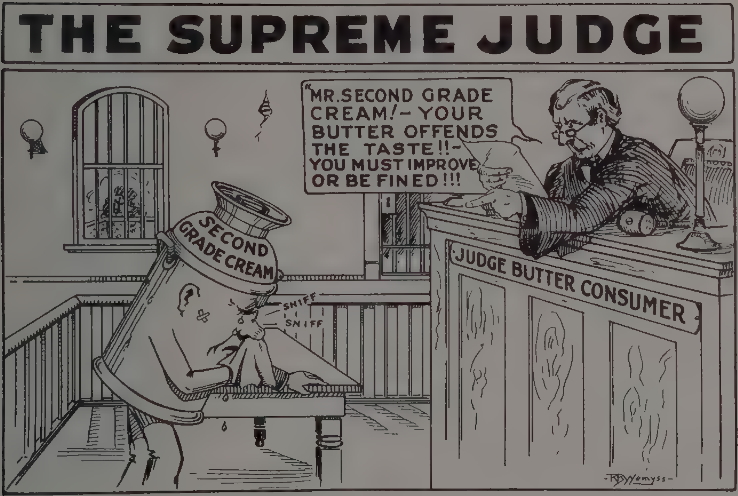
CREAM GRADING ON THE FOUR DAY DELIVERY PLAN IN INDIANA



THE SUPREME JUDGE
"MR. SECOND GRADE CREAM! – YOUR BUTTER OFFENDS THE TASTE!! – YOU MUST IMPROVE OR BE FINED!!!
SECOND GRADE CREAM
SNIFF
SNIFF
JUDGE BUTTER CONSUMER

The age of cream is the foremost factor causing second grade cream and poor quality butter. Marketing cream from the farm on the basis of the Four Day Delivery Plan will improve the quality and make possible the manufacture of butter of a quality satisfactory to the consumer demand.

CREAM GRADING ON THE FOUR DAY DELIVERY PLAN IN INDIANA

V. C. MANHART
Dairy Department

Grading cream on the Four Day Delivery Plan has effected an improvement in the marketing of cream for buttermaking of great consequence to the butter industry of southern Indiana. Introduced in its present form during the spring of 1927, the plan has since operated continuously and with splendid results. Prior to four day grading, it was the common practice of cream producers to sell their cream but once a week although many accumulated their product for a period of ten days or more before marketing it. Less than 20% of the cream was marketed at intervals of four days or less. The introduction of four day grading immediately produced a radical change as evidenced by the results of the first month of grading when 53.9% of the cream was marketed at intervals of four days or less. This percentage has gradually increased to the point where 75.6% was so marketed in the corresponding period of the year, 1932. The benefit to the industry of this change in cream marketing practice is certainly not over-estimated by the most enthusiastic advocate of four day grading.

The Four Day Plan has exerted a stabilizing influence upon the butter industry in southern Indiana that has benefited all agencies connected with the industry. Cream producers who produce a quality product are rewarded with a premium. Over a third of a million dollars has been paid in premiums to farmers of eighteen Indiana counties during the past five years as a result of four day grading. The Four Day Plan has established a uniform system of buying cream on a grade basis with a tangible standard, the four day limit, that cannot be misconstrued by the buyer nor misunderstood by the producer. The quality of cream is improved, thereby making possible the manufacture of a good grade of butter that satisfies the general requirements of the present day consumer demand, and enables the creamerymen to pay the producer a higher price for butterfat. Thus the benefits of four day grading are distributed among all agencies interested in the butter industry; particularly the cream producer, butter manufacturer, and the cream buyer.

The responsibility of cream quality improvement rests upon the aforementioned agencies among which there must be whole-hearted cooperation if a quality program is to be satisfactorily completed. In order that the Four Day Delivery Plan function properly and produce the maximum benefits to all, it is necessary that these agencies be familiar with—and abide by—the principles of the plan, its rules and regulations.

FOUR DAY GRADING SOUND IN PRINCIPLE

Cream grading on the Four Day Delivery Plan is sound in principle. The requirement, that premium cream be delivered at intervals not to exceed four days, is based on the results of experiments conducted by the Dairy Department of the Purdue University Agricultural Experiment Station.[1] These experiments showed that the depreciation in the quality of cream, held under ordinary farm conditions, progressed more rapidly after the fourth day of accumulation than at any stage prior to the fourth day.

Subsequent investigations have been conducted in the Indiana grading territory where cream for investigational purposes was secured through the regular channels of procurement employed by the creameries operating in the territory.[2] These experiments consisted of churnings made from two grades of cream purchased by ten cream buying stations located in the Southern Indiana Four Day Grading Territory. The grade of cream was determined by the age, no consideration being given to flavor or odor except that cream containing onion or garlic flavor was rejected for experimental purposes. The two grades were designated as Premium and Regular cream. The Premium grade being cream sold at intervals of four days or less, while the Regular grade was cream sold at intervals of more than four days.

The cream station operators shipped the cream in the usual manner to the creamery for which they purchased the cream. Each of the two grades as purchased by the individual stations was churned separately at the creamery without further grading. The resulting butter was shipped to a Chicago butter firm where it was scored by one of their inspectors and by the Federal Butter Inspector.

The results of these investigations showed an appreciable difference in quality, the butter made from Premium cream scoring about 1¼ points higher than that made from Regular cream. These data show conclusively the justification of a maximum limit of four days in the frequency of delivery of Premium cream by the producer.

GRADES OF CREAM ACCORDING TO FOUR DAY PLAN

There are four grades of cream under the Four Day Plan. These grades are as follows:

Premium cream that which is sold at intervals of not more than four days and is free from undesirable flavors and odors at the time of delivery.

Regular cream that which is sold at intervals of more than four days; and cream sold at intervals of four days or less that contains undesirable flavors and odors, but is not of such quality as to warrant placing it in the onion or rejected grade.

Onion cream that which has an onion or garlic flavor.

Rejected cream that which is rancid, moldy, dirty, oily, or otherwise unwholesome. Cream of this grade will not be accepted or purchased under any condition by creameries.

BASIS OF PAYMENT FOR DIFFERENT GRADES OF CREAM

The quotations of prices on the different grades of cream by individual creameries are applied as follows:

The **premium cream price** quoted by individual creameries to their cream buyers and patrons shall be paid only for the Premium grade of cream as defined by the four day cream grades. Furthermore, each patron to whom the premium price is paid must have a four day record tag properly filled out and attached to his cream container. In case the cream is purchased by a cream station, the operator must detach this tag from the patron's cream container, fill in the final record on it, and send the completed tag with his buying report to the creamery for which the cream is purchased. All buyers of cream must follow this procedure in order to receive full reimbursement from the creamery for their Premium cream purchases.

The **regular cream price** quoted by individual creameries to their cream buyers and patrons shall be paid only for Regular grade cream as defined by the four day cream grades. Creameries allow no exception to this rule for their cream buyers, and the cream buyer will be reimbursed by the creamery for cream purchases of Regular grade only on the basis of the regular cream price as quoted by the creamery.

The **onion cream price** quoted by individual creameries to their cream buyers and patrons shall be paid only for the Onion grade of cream as defined by the four day cream grades. In case a buyer for a creamery should pay more than the onion cream price quoted by the creamery for cream that is found at the creamery to contain an onion or garlic flavor, the creamery will not reimburse the buyer for the excess payment.

No quotation is made for cream that comes under the classification of Rejected cream as defined by the four day cream grades. The creameries will not accept cream of this grade and cream buyers should not purchase such cream at any price since it is unwholesome and not suitable for human consumption.

GRADING SUPPLIES REQUIRED FOR BUYING CREAM ON THE FOUR DAY PLAN

All creameries and their cream buyers should be equipped with the standard four day grading supplies used in the territory. Cream buyers are furnished these supplies by the creamery for whom they purchase the cream. The proper use of these supplies will insure efficient handling of the cream at the time of purchase without undue trouble on part of the buyer and will prevent confusion of the grades of cream while in the buyer's hands and when it arrives at the creamery.

Four day supplies required by cream stations. The standard supplies that are essential to proper grading on the Four Day Plan at cream buying stations are as follows:

1. Four day tags, to be attached to the cream container of the producer as a means of ascertaining the date of the last cream delivery made by him. The form of this tag is illustrated by figure 2 which shows both sides of the tag properly filled in.

2. A dater stamp with pad, which is used to stamp the dates on the four day tags.

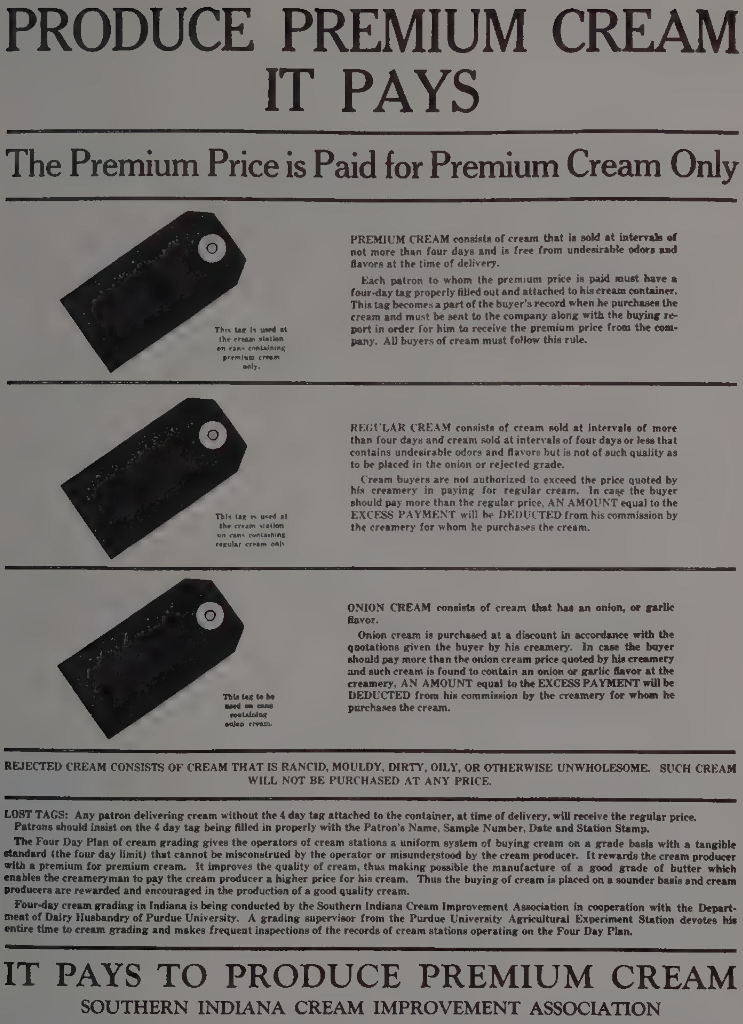
BACK SIDE

Fig. 2. The Four Day Tag is attached to the producer's cream container as a means of ascertaining the date of the last sale of cream, thereby making possible the determination of the age of the cream by the purchaser. The illustration shows both sides of the tag properly filled in.

3. A company stamp, used by the cream station operator to facilitate the identification of his purchases when they arrive at the creamery. It contains the number of the cream station and the name of the creamery for which the cream is bought. The cream station number is fixed by the creamery. Each station being given a different number as a means of identifying the buyer of the cream rather than depend upon the station operator's signature which may be illegible.

4. Signal tags, of three different colors, namely: blue, red, and yellow. These tags are used by the cream buyer to identify the different grades of cream. The blue colored tags are attached to the creamery shipping cans containing the premium grade of cream, the red tags are used on cans containing regular grade cream, and the yellow tags are used on cans containing onion cream. The proper tag should be attached by the station operator, to the shipping can as soon as it is put into use at the station, so as to avoid any confusion among different grades of cream.



PRODUCE PREMIUM CREAM IT PAYS

The Premium Price is Paid for Premium Cream Only

This tag is used at the cream station on cans containing premium cream only.

PREMIUM CREAM consists of cream that is sold at intervals of not more than four days and is free from undesirable odors and flavors at the time of delivery.

Each patron to whom the premium price is paid must have a four-day tag properly filled out and attached to his cream container. This tag becomes a part of the buyer's record when he purchases the cream and must be sent to the company along with the buying report in order for him to receive the premium price from the company. All buyers of cream must follow this rule.

This tag is used at the cream station on cans containing regular cream only.

REGULAR CREAM consists of cream sold at intervals of more than four days and cream sold at intervals of four days or less that contains undesirable odors and flavors but is not of such quality as to be placed in the onion or rejected grade.

Cream buyers are not authorized to exceed the price quoted by his creamery in paying for regular cream. In case the buyer should pay more than the regular price, AN AMOUNT equal to the EXCESS PAYMENT will be DEDUCTED from his commission by the creamery for whom he purchases the cream.

This tag to be used on cans containing onion cream.

ONION CREAM consists of cream that has an onion, or garlic flavor.

Onion cream is purchased at a discount in accordance with the quotations given the buyer by his creamery. In case the buyer should pay more than the onion cream price quoted by his creamery and such cream is found to contain an onion or garlic flavor at the creamery, AN AMOUNT equal to the EXCESS PAYMENT will be DEDUCTED from his commission by the creamery for whom he purchases the cream.

REJECTED CREAM CONSISTS OF CREAM THAT IS RANCID, MOULDY, DIRTY, OILY, OR OTHERWISE UNWHOLESOME. SUCH CREAM WILL NOT BE PURCHASED AT ANY PRICE.

LOST TAGS: Any patron delivering cream without the 4 day tag attached to the container, at time of delivery, will receive the regular price. Patrons should insist on the 4 day tag being filled in properly with the Patron's Name, Sample Number, Date and Station Stamp.

The Four Day Plan of cream grading gives the operators of cream stations a uniform system of buying cream on a grade basis with a tangible standard (the four day limit) that cannot be misconstrued by the operator or misunderstood by the cream producer. It rewards the cream producer with a premium for premium cream. It improves the quality of cream, thus making possible the manufacture of a good grade of butter which enables the creameryman to pay the cream producer a higher price for his cream. Thus the buying of cream is placed on a sounder basis and cream producers are rewarded and encouraged in the production of a good quality cream.

Four-day cream grading in Indiana is being conducted by the Southern Indiana Cream Improvement Association in cooperation with the Department of Dairy Husbandry of Purdue University. A grading supervisor from the Purdue University Agricultural Experiment Station devotes his entire time to cream grading and makes frequent inspections of the records of cream stations operating on the Four Day Plan.

IT PAYS TO PRODUCE PREMIUM CREAM

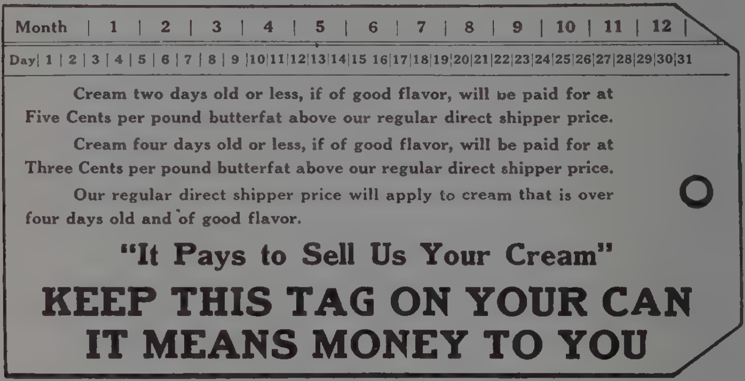
SOUTHERN INDIANA CREAM IMPROVEMENT ASSOCIATION

Fig. 3. A poster explaining the Four Day Delivery Plan of grading cream to the producer should be posted at the buying station. The poster illustrated presents the grading plan to the producer so that there will be no misunderstanding concerning the grading of his cream.

5. The poster entitled, "Produce Premium Cream—It Pays." This poster, illustrated by figure 3, explains the Four Day Delivery Plan of grading cream to the producer. It should be posted on the wall of the cream station in a conspicuous place where the producer may read it. This poster presents the grading plan to the producer so that there will be no misunderstanding concerning the grading of his cream. It largely relieves the station operator of the responsibility for not making concessions by classifying cream as a higher grade than it actually merits.

Direct shipper, local delivery, and route cream. Cream shipped direct to the creamery by the producer, delivered by the producer to the creamery, or gathered by truck routes may be purchased on the Four Day Plan as readily as station cream. The same supplies required at buying stations are needed by the creamery for grading cream procured through these different channels.

A special shipping tag may be used in place of the regular four day tag for cream shipped direct to the creamery by the producer. This tag must provide a means of ascertaining the date of the last sale of cream by the shipper. A form that serves this purpose very satisfactorily is illustrated by figure 4. One side of the tag is printed according to the common form used for direct shipper tags. The other side of the tag provides for a record of the date the cream was purchased by the creamery. The date of the cream purchase is indicated by punching the proper month and date listed at the top of the tag. The tag is then attached to the empty can just prior to shipping it back to the producer. The tag is returned with the can by the producer when he makes his next cream shipment. Thus the creamery purchasing the cream is able to determine the age of the cream.



Month | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |

Day | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31

Cream two days old or less, if of good flavor, will be paid for at Five Cents per pound butterfat above our regular direct shipper price.

Cream four days old or less, if of good flavor, will be paid for at Three Cents per pound butterfat above our regular direct shipper price.

Our regular direct shipper price will apply to cream that is over four days old and of good flavor.

"It Pays to Sell Us Your Cream"

KEEP THIS TAG ON YOUR CAN
IT MEANS MONEY TO YOU

Fig. 4. A special shipping tag that may be used in place of the four day tag when cream is shipped direct to the creamery by the producer. The side of the tag shown in the illustration provides for a record of the date the cream was purchased by the creamery. The other side of the tag is printed according to the common form used for direct shipper tags.

The regular four day tag is accepted by the creamery as proof of the date of the last cream sale by the producer in case he has no direct shipper tag, as may occur when the cream has been marketed through some other channel on the previous occasion.

USE OF THE FOUR DAY TAGS

The success of the Four Day Plan is largely dependent upon the proper use of the four day tag. The use of the tag avoids any misunderstanding between the cream buyer and his patron concerning the interval of delivery. It enables the cream producer to sell his cream to any creamery or cream buyer, operating on the Four Day Plan, and secure the premium price since the date of the previous delivery is recorded on the tag which is attached to his cream container. By means of the four day tag and the cream buyer's record of cream purchases, the creamery and cream grading supervisor can check on the interval of delivery and thus prevent buyers from paying the premium price to producers who are not entitled to it from the standpoint of the frequency of delivery. Thus all cream buyers are placed on the same basis for buying cream and one buyer cannot readily take advantage of another by favoring certain cream producers.

Instructions for filling in four day tags. It is recommended that the dater and creamery stamps, previously described, be used in filling in the four day record tags. These stamps effect a considerable saving of time for the buyer, since they leave only the name and address of the producer and the sample number of his cream test to be filled in by pen or pencil. Errors are also avoided by the use of the stamps, and the date and the identification of the buyer's agency are more likely to be legible than when filled in by pencil.

A four day tag properly filled out on both sides is illustrated by figure 2. The tag is first filled in by the station operator on the face side as shown in figure 2 and then attached to the empty cream container of the producer. The producer must leave the tag, thus filled in, on his container until his next sale of cream. The cream buyer will detach the tag from the container at that time.

Suppose the next sale of cream by this particular producer was on April 6, 1932. The buyer to whom he sells the cream will detach the four day tag from the container and note as illustrated in figure 2 that the producer, "John Doe" of "Jamestown" last sold cream on "April 2, 1932," to station number "10" of the "Purdue Creamery" and that his cream sample number was "21" on the operator's buying report. The present buyer of the cream will then turn the tag over and stamp the date "April 6, 1932," and write the cream sample number "45" on the back side of the tag as illustrated. (This date and sample number must agree with the date and sample number on the operator's buying report which is sent to the creamery.) The record on the tag will then be complete and the buyer can tell from it whether or not the cream has been sold at an interval of four days or less. In this case the interval is four days and John Doe is entitled to the premium price, if his cream is free from undesirable flavors and odors. The buyer must send the completed tag with his daily buying report to the creamery for which he purchases the cream. Thus the creamery has a complete record of the transaction between the cream buyer and the producer. A new tag is filled in on the face side and attached to the producer's cream container by the station operator in place of the old tag that he removes.

Miscellaneous rules concerning four day tags. In further explanation of the use of four day tags the following rules of the Southern Indiana Cream Improvement Association are quoted.

1. A cream patron in order to receive the premium price must have a four day tag properly filled out and attached to his cream container. If the interval since his previous delivery of cream as shown on the tag does not exceed four days and the cream is free from undesirable flavors and odors, the patron is entitled to the premium price.

2. Whenever a patron delivers a container of cream to which there is no four day tag attached, the cream buyer must pay the regular price. When the producer, whose container is without a tag, has delivered cream to the same

buyer within a period of four days the buyer shall notify the creamery of such facts giving dates of both deliveries and if the creamery company finds that according to its records the patron is entitled to the premium, the creamery will instruct the buyer to make adjustment on the amount due.

3. The cream buyer must attach a four day tag to the patron's container for each entry on his buying report or record.

4. At the time the four day tag is attached to the patron's empty cream container, the patron's name, residence, and cream sample number must be placed on the tag by the cream buyer, also the date, the cream station number, and the name of the creamery. When the tag is detached from the patron's cream container at the time of his next sale of cream, the date of the sale and the patron's cream sample must be filled in on the opposite side of the tag by the buyer; and the completed tag must be sent to the creamery along with the operator's buying report.

5. The dates on all cream station daily buying reports must agree with the dates on the checks and on the four day tags, and such dates must be the actual date that the cream is received at the cream station. In case more than one buying day is listed on a single sheet of the buying report the operator must write in the date above the name of the first patron on each buying day.

6. Cream delivered to a cream station after the station has closed for the day must be entered on the buying report for the following day and the four day tags dated accordingly. Thus cream delivered on the fourth day to a cream station that has closed for the day will not appear on the station's buying report until the following day which will make the interval of delivery five days, consequently the premium price cannot be paid for the cream.

USE OF THE COLORED SIGNAL TAGS

The colored signal tags are used for the identification of shipping cans containing the different grades of cream, the blue tag indicating Premium cream, the red tag Regular cream, and the yellow tag Onion cream. These tags are attached by the cream buyer to the shipping cans at the cream station at the time the cream is purchased. Premium cream purchases are then poured from the producer's container into a shipping can bearing a blue signal tag, Regular cream purchases into a shipping can bearing a red signal tag, and Onion cream into a shipping can bearing a yellow tag. The different grades of cream must not be mixed under any circumstances, and the signal tags must be left on the shipping cans when the cream is shipped to the creamery.

Ruling concerning use of colored signal tags. The proper use of signal tags at the cream station lessens the possibility of the operator mixing different grades of cream by mistake, also they demonstrate to the producer that different grades of cream are kept separate. Signal tags are therefore an important adjunct of the Four Day Plan and the following ruling is used to enforce the use of the tags and emphasize their importance.

1. In the case of cream contained in cans which are not designated with the proper signal tags indicating the grade of the cream, or cans without signal tags, deductions will be made from the station operator's wages or buying commission according to one of the two following methods:

Option (a)—An amount equal to the differential between the Premium and Regular cream price will be deducted from the station operator's wages or buying commission for each pound of butterfat contained in cans that are not designated with the proper signal tag of its grade, or are without signal tags.

Option (b)—No buying commission will be allowed the cream buyer on purchases of cream contained in cans which are not designated with the proper signal tags or are without signal tags.

GRADING CREAM IN ACCORDANCE WITH THE QUALITY REQUIREMENTS OF THE FOUR DAY PLAN

In grading cream on the Four Day Plan there are two requirements that must be fulfilled before cream can be rightfully purchased as Premium grade, namely: (1) the cream must be marketed at intervals of four days or less, (2) the cream must be free of undesirable flavors and odors at the time of purchase. Too many cream buyers are prone to neglect this latter requirement and depend entirely upon the age limit in their grading. This practice materially reduces the benefits of Four Day grading since not all cream delivered at intervals of four days or less is of premium quality. Such cream may contain flavors that prohibit its use in the manufacture of a good quality butter. In view of this fact, cream containing pronounced off-flavors must be graded as Regular, Onion, or Rejected according to the nature and degree of the flavor defect even though the cream may have been delivered at intervals of four days or less. The economic loss resulting from mixing an occasional purchase of under-grade cream with purchases of good cream provides sufficient grounds for condemnation of the practice of grading entirely on an age basis. One can of kerosene or onion flavor cream will spoil an entire churning at the factory. Likewise, one small purchase of off-flavor cream mixed with good cream at the buying station will spoil the entire contents of a ten gallon shipping can. For this reason each individual cream purchase must be tasted and graded on the basis of its flavor before it is mixed with other purchases. This precaution will serve as a safeguard against the spoilage of premium quality cream by the addition to it of cream of inferior quality.

The detection of off-flavors can be accomplished only by tasting the cream. True, some individuals have keener senses of taste and smell than others. Consequently, they are more adept at detecting undesirable flavors in cream than others. Nevertheless the average individual can become a satisfactory grader of cream by acquainting himself with the fundamentals of grading and exercising due care.

Cream grades at the butter factory are primarily based upon the quality of butter that can be made from the cream of a particular grade. For example it is recognized that the manufacturer of butter of the best quality, known on the market as Extras, requires the use of sweet cream. Thus the highest grade of cream is generally designated as Sweet cream. The grade of butter next below Extras is Firsts, consequently the grade of cream next below Sweet is First. Likewise we have a Second grade cream corresponding to butter of the quality known as Seconds, and an Under or Third grade corresponding to butter of the quality known as Thirds. Third grade cream is the poorest quality that is acceptable for butter making. Cream that is inferior to Third grade is commonly recognized as being unwholesome and is not used in the manufacture of butter. Such cream is termed Reject.

The cream grades enumerated have definite requirements to be met before cream can be placed in a specified grade. Not all cream that is sweet to taste will grade as Sweet cream. In addition to being sweet it must be fresh, clean to taste, and free of all undesirable flavors. The reason for these qualifications is that if sweet cream is not fresh, clean to taste, and free from undesirable flavors it will not make butter of the quality known as Extras. Thus in grading cream we must know the requirements for each grade and then depend upon the keenness of our senses of taste and smell to determine whether the cream will qualify according to the requirements of a specific grade. These minimum grade requirements are as follows:

Sweet cream. (Extra Premium quality) cream must be sweet, fresh, clean to taste, and free of all undesirable flavors.

First grade cream. (Premium quality) moderately sour cream that is free of objectionable flavors, and clean to taste; or sweet cream that contains traces of such objectionable flavors as cowy, barny, and feed or weed flavors other than onion and garlic.

Second grade cream. (Regular quality) sour cream that is musty, yeasty, stale, bitter, greasy, or a trifle metallic to taste; or contains objectionable flavors such as cowy, barny, feed or weed flavors other than onion and garlic. Sweet cream that is musty, yeasty, stale, bitter, or greasy to taste; or contains any objectionable flavor to a degree that disqualifies it from a higher rating.

Third, or Under grade cream. (Onion quality) cream that is tallowy, cheesy, exceedingly stale, sour, or metallic; and cream that contains garlic, onion, or other off and foreign flavors to a degree that disqualifies it from a higher rating.

Reject cream. Cream that is very old, rancid, moldy, dirty, and cream that is contaminated with gasoline, kerosene, lubricating oil, or is otherwise unwholesome, is not acceptable to creameries for buttermaking; consequently cream buyers will not purchase cream of this nature.

Items other than flavor to be considered in grading cream. The grade requirements for cream given above are based entirely on flavor. Although flavor is by far the most important item affecting the quality of cream, there are other items to be considered in grading cream, namely: body, acid content, butterfat content, and cleanliness.

The body of cream is judged by observing the physical condition. Cream with a good body is smooth, free from lumps, and of uniform consistency. Cream that is mealy, slightly lumpy or curdy is objectionable. When these defects are pronounced, or if the cream is partly churned, the quality of the cream is generally that of Second grade and the cream should be so graded. Cream that is wheyed off, or is otherwise abnormal in body should be rejected since the quality of such cream generally will not warrant its purchase. Body defects such as curdy, lumpy, or partly churned, in addition to affecting the quality of the cream, are also detrimental to the determination of the butterfat content. It is quite difficult, and often impossible, to obtain a correct test on such cream since the abnormal condition prevents accurate sampling of the cream.

The acid content of cream is considered when judging the flavor. Sweet cream contains not more than 0.2 per cent acid. The maximum acidity limit commonly accepted on First grade cream is 0.6 per cent. Cream containing more than 0.6 per cent acid is generally graded Second or Third according to the degree of acidity and the flavors associated with high acid. The acid content of cream is an important factor affecting the desirability of cream for buttermaking. Other than the fact that high acid is generally associated with cream of poor quality as a whole, high acid also complicates the processing of cream for buttermaking, tends to promote the development of flavor defects in butter, and adversely affects the keeping quality of butter.

Richness or fat content of cream is another item that must be considered in the judging of the desirability of cream for buttermaking. Cream testing from 33 to 35 per cent is most desirable for churning under present day conditions. Low testing cream is disfavored since it generally deteriorates in quality more rapidly than high testing cream, also it takes skimmilk away from the farm and increases the cost of transportation per pound butterfat from the farm to the factory. On the other hand when cream is unduly rich in fat, the mechanical loss in handling is increased since more cream adheres to the utensils. Such cream also makes accurate sampling for the fat test difficult, particularly in cold weather when the cream may become so thick that it is impossible to mix it thoroughly by stirring without previously warming the entire contents of the can. Thus the fat test on cream of high fat content is often inaccurate.

Cleanliness in the production and handling of cream is a requirement that should need no explanation. The condition of both the cream and container should indicate unmistakable cleanliness, and cream so lacking in cleanliness, or contaminated with foreign matter, as to be unwholesome is not acceptable by creameries and should not be purchased by cream buyers.

Technic of cream grading. Most cream buying stations and many creameries are not adequately equipped to grade cream in accordance with the standards applicable to the handling of food products. The practice of removing the remnants of cream from the stirrer by drawing the rod through the hand and then tasting the cream by dipping the fingers or hand into the cream is obnoxious and intolerable from the standpoint of sanitation and ordinary decency. Too often the creamery management is to blame for such practices because of failure to provide its graders and buyers with the proper equipment to grade cream.

The first step in grading cream is to stir it thoroughly. It is recommended that the stirring be done with a stirrer having a perforated disc at the lower end so as to facilitate the drainage of the cream from the stirrer back into the can. In addition to the perforated disc the stirrer should have a slide, with handle attached, for the purpose of removing the remnants of cream from the rod of the stirrer. This slide is held by its handle at the top of the stirrer rod while the cream is being stirred. Upon completion of the stirring, the slide is moved down over the rod by means of the hand and thus removing the cream remaining on the rod and permitting it to drain from the perforated disc back into the can. The odor of the cream may be noted at the time the lid is removed from the cream container and again immediately after stirring. The cream sample for the butterfat test may also be taken immediately after stirring and thus make one stirring serve for both the grading and fat test samples.

A glass rod about six inches in length and three-eighths inch in diameter is quite satisfactory for obtaining a small amount of the cream for the purpose of tasting it at the time of grading. Such a rod when dipped into the cream and withdrawn will retain about the right amount of cream for tasting. The rod should be rinsed in hot water after tasting each can of cream and before proceeding to the next can. Rinsing of the rod between samples is a sanitary measure that should be observed; furthermore it is important, from the standpoint of accurate grading, to so rinse the rod since the possibility of carrying objectionable flavors from one can of cream to another is lessened. To simplify the rinsing of the glass rod it is advisable to have two or more rods in a vessel of hot water and use them in rotation, thus providing a clean rod for each can of cream to be graded.

The cream should be held in the mouth, when tasting it, long enough to obtain all flavors that it may possess. Then expectorate the cream after tasting into a dental spittoon or a vessel containing saw-dust or other suitable material. The vessel should be emptied at frequent intervals, at least daily, cleaned and the saw-dust replaced with fresh. A dental spittoon is recommended particularly for the receiving rooms of butter factories because of the large quantity of cream graded daily therein. The spittoon should be portable and equipped with a warm water cup so fitted that clean warm water will circulate through the cup and then pass from the cup to the bowl of the spittoon, flow over its inner surface and out of the bottom to a drain in the floor.

Cream graders who follow the technic recommended and are equipped with the grading apparatus mentioned in the foregoing paragraphs will usually prove more effective in their grading than will be the case when little or no facilities for proper grading are provided. Furthermore, the satisfaction of having placed the grading of cream on a sanitary basis and the consequent effect upon the cream producer will more than repay for the slight cost and extra effort expended.

Ruling concerning quality requirements of cream. Due to the fact that many buyers of cream on the Four Day Plan tend to slight the grading of cream on the basis of the senses of taste and smell, it has been found necessary by some creameries to resort to the following ruling in order to prompt their cream buying agents to give more attention to that phase of cream grading.

1. In the case of cream purchased as Premium at a buying station and grading Second at the butter factory, a deduction will be made from the station operator's wages or buying commission according to one of the two following methods:

Option (a)—An amount equal to the differential between the Premium and Regular cream price will be deducted from the station operator's wages or buying commission for each pound of butterfat purchased as Premium that graded Second at the butter factory.

Option (b)—No buying commission will be allowed a station operator on cream purchased as Premium at the buying station and grading Second at the butter factory.

THE CREAM IMPROVEMENT ASSOCIATION

Prior to introducing the Four Day Plan in a locality an organization of creameries should be formed for the purpose of providing for such administrative, educational, and supervisory services necessary for the successful operation of the plan. An organization of this nature is essential. Without the cooperation of a majority of the creameries operating in the grading territory, and adequate educational work and supervision, there is but little chance for successful operation of the plan.

A cream improvement association formed for the purpose of promoting quality improvement by means of Four Day grading should be a voluntary organization with its membership open to all concerns buying cream in the grading area. The functions of the association should be in accordance with the policies and methods of some public agency concerned with dairying such as the State Agricultural College or the Office of the State Dairy Commissioner. This necessitates close contact with the activities of the association by the public agency. The relations of the public agency to the affairs of the association, however, should be of an advisory nature. A written agreement stating the functions of both the association and the public agency is desirable. The following form of an agreement is used by the Indiana cream improvement associations.

MEMORANDUM OF AGREEMENT
between the
NORTHWESTERN INDIANA CREAM IMPROVEMENT ASSOCIATION
and the
PURDUE UNIVERSITY AGRICULTURAL EXPERIMENT STATION

MEMORANDUM OF AGREEMENT, made this......................day of the month of ...., of the year.............; between the NORTHWESTERN INDIANA CREAM IMPROVEMENT ASSOCIATION with seat of business in the city of ...., in the county of..................................., and the state of Indiana; and the PURDUE UNIVERSITY AGRICULTURAL EXPERIMENT STATION with seat of business in the city of West Lafayette, in the county of Tippecanoe, and the state of Indiana.

The Northwestern Indiana Cream Improvement Association, hereafter termed "The Association" is represented herein as a voluntary organization formed for the expressed purpose of improving the quality of cream marketed in northwestern Indiana, and consisting of the following concerns:

(Names of Members of the Association)

THE ASSOCIATION AGREES:

(1) To furnish a fund of sufficient amount to properly conduct such administrative, educational, and supervisory services necessary for the improvement of the quality of cream produced for buttermaking in the northwestern section of the state of Indiana for a period of one year.

(2) To pay the Purdue University Agricultural Experiment Station...................... dollars from the aforesaid fund for the purpose of paying the salary of a man to be engaged by the Agricultural Experiment Station to conduct cream improvement work in the northwestern section of the state of Indiana, said...............................dollars to be paid as follows: ....dollars on or before the...........day of the month of..........................., of the year..........., and......................... dollars on or before the tenth day of each month thereafter until the total sum of............ ....dollars has been paid the Agricultural Experiment Station.

(3) That the remainder of the fund provided for under item (1) will be in the possession of an agent of The Association and that said agent will use such remainder of the fund to pay all expenses, other than salaries, in connection with the cream improvement work.

(4) That the policies and methods of The Association will be in accordance with the policies and methods of the Purdue University Agricultural Experiment Station and under the supervision of the Department of Dairy Husbandry of the Purdue University Agricultural Experiment Station.

THE PURDUE UNIVERSITY AGRICULTURAL EXPERIMENT STATION AGREES:

(1) To select and employ a man for the purpose of promoting cream improvement in the northwestern section of the state of Indiana for a period of twelve months. The salary of said person shall be..................................dollars per annum, which sum will be furnished as heretofore provided for by The Association.

(2) To supervise the policies and methods of The Association through the Department of Dairy Husbandry of the Purdue University Agricultural Experiment Station as provided for under item (4) of the agreement on the part of The Association.

SIGNED:

Northwestern Indiana Cream Improvement Association,
(Signatures of the individual members of the Association)
Purdue University Agricultural Experiment Station,
....

The signing of the foregoing agreement by a majority of the creameries operating in the proposed grading area and the public agency chosen to assist in the cream quality improvement program is usually the first step in the organization of the cream improvement association. A chairman and secretary-treasurer may then be elected by members of the association and plans be made for the actual introduction of the Four Day Plan.

The fund to be furnished by the association for the purpose of conducting the administrative, educational, and supervisory services in connection with the Four Day Plan is raised by an assessment based upon the butterfat purchases in the proposed grading area. The rate of assessment per pound butterfat is determined by the size of the fund necessary and the volume of butterfat purchased in the grading territory. A fund of about $5,000 per year has been required to conduct the grading work in the southern Indiana grading territory consisting of eighteen counties. Present price levels and salaries however will materially lower this cost. The average rate of assessment for the Southern Indiana Association has been less than one-fourth cent per pound butterfat. The fund so raised is used to provide for the salary of a grading supervisor, pay his traveling expenses, the administrative expenses involved in transacting the business of the association, and conduct educational work relative to cream quality improvement.

Regular monthly meetings of the association have proven of great value as a means of keeping the grading work operating smoothly. The grading supervisor makes his reports at these meetings. Thus grading difficulties may be disposed of and violations of the grading rules and regulations brought to the attention of the offender. The cooperation of the members of the association and their regular attendance at the association meetings are important factors pertaining to the effectiveness of the grading supervisor's work and successful operation of the Four Day Plan.

THE CREAM GRADING SUPERVISOR

One of the foremost requisites for successful grading of cream on the Four Day Plan is the services of a capable grading supervisor. The work of the supervisor is conducted mostly in the field. His duties are varied. He must be well versed in the dairy industry and should be preferably a four year graduate in dairying from the State Agricultural College. Diplomacy, sincerity, technical knowledge, tact, personality, and taciturnity with respect to the businesses of the members of the association are special traits to be considered in selecting a supervisor. The supervisor should be employed by a public agency cooperating with the association on the cream improvement program, and should work under the joint direction of the public agency and the chairman of the association. Being so employed and directed enables the supervisor to more readily gain the confidence of both creameries and cream producers since his status is that of an unbiased party.

The duties of the supervisor may be grouped into four general classes, namely: (1) to check all sources of cream procurement within the grading territory to see that cream is being purchased strictly in accordance with the rules and regulations of the Four Day Plan, (2) to ascertain if all creameries cooperating in the grading work are checking the purchases of their buyers with respect to Four Day grading and otherwise observing the rules and regulations pertaining to grading, (3) to explain the principles of the grading plan to producers and buyers and keep county agricultural agents and other public agencies in touch with the grading work, and (4) to report the results of his work at regular intervals and keep the public agency, employing him, and the chairman of the association informed as to his activity.

A large part of the supervisor's time should be devoted to inspectional work among cream buyers throughout the grading territory. He should first

Grading Supervisor

Remarks:

Fig. 5. Form of report used by the cream grading supervisor in reporting inspections at buying stations and creameries. Copies of the report are given to the creamery for which the cream is purchased, the chairman of the association, and the public agency employing the supervisor.

ascertain that all buyers fully understand the Four Day Plan and how it operates. Subsequent inspections should be made frequently in order to ascertain whether the buyers are operating in accordance with the rules and regulations of the grading plan. Such inspections are facilitated by a report blank which the supervisor is required to fill in at the time of each inspection. Copies of the report are given to the creamery for which the cream is purchased, the chairman of the cream improvement association, and the public agency employing the supervisor. The form of the supervisor's report blank is illustrated by figure 5. These reports keep the association and public agency in close touch with the work of the supervisor and inform them of the conditions throughout the grading territory.

The supervisor should be careful not to exceed the limitations of his duties when cases of irregularities in grading are discovered. His task is to discover such irregularities and report them to the proper persons. The responsibility of correcting the situation rests with the creamery for which the cream is purchased. Should the creamery fail to accept this responsibility, the supervisor should report in detail the facts of the case to the chairman of the cream improvement association and the public agency cooperating with the association in the cream improvement work. Thus the supervisor is not an enforcement agent. However, when grading irregularities on part of a cream buyer are discovered, the supervisor should keep in close contact with both the creamery and the buyer until the situation is settled.

It is well for the supervisor to call at the offices of the creameries at regular intervals to ascertain if the Premium cream purchases of the buyers are being checked. This work is generally assigned to the clerical help of the creamery. Frequently, the regular work of the office leaves little time for the checking of the four day tags sent in by the cream buyers. Under such circumstances the checking may be neglected. The result is that irregularities in the grading of buyers are not discovered until the supervisor makes his inspection. Some buyers may consequently became lax in their grading under such conditions. Cream that is over four days old may be purchased as Premium, and four day tags may be faked by the buyers or other methods employed to evade the grading plan so as to pay the premium price for Regular grade cream. For these reasons, the supervisor should endeavor to have the tags checked systematically at the creamery by some person who can be depended upon to do this work conscientiously. He should also call frequently at the creamery office and discuss the grading work with the person doing the checking so as to stimulate interest in the grading work.

One phase of the supervisor's work that is often neglected, yet of much importance, is that of selling the grading plan to producers, cream buyers, county agricultural agents, and other public agencies. The introduction of the grading plan in a territory without proper educational work preceding and accompanying it will generally lead to criticism, regardless of its merits. Farmers may regard it as a selfish move on the part of creameries at the expense of the producer. Agricultural agents if not acquainted with the principles of the plan and its purpose will be indifferent and not in a position to discuss it with the farmers. Cream buyers, who are chiefly concerned with volume since they usually work on a commission basis, may oppose grading for fear that it will curtail their purchases and give competitors an advantage.

On the other hand, if the producers and agricultural agencies are informed and kept in touch with the cream improvement program the support of the progressive minded producers may be obtained. Although the supervisor may find that other duties make a heavy demand upon his time, he should so plan his work that sufficient opportunity is left for the advancement of the grading work by educational methods. Producers should be interviewed and informed of the necessity for cream grading and the merits of the Four Day Plan. Inspections of buyers' purchases should be made in a manner that will tend to create cooperation between the buyer and the supervisor. Care should be taken that the cream buyer is not given the impression that the supervisor is solely an inspector searching for something that is wrong. The inspector should be sympathetic with the buyer's difficulties and endeavor to aid him in solving his problems. Proper attention to the advancement of the Four Day Plan by educational methods will do much towards establishing the plan on a sound basis and lessen irregularities in the grading of cream.

The supervisor is largely relied upon by the public agency and the association for information relative to the progress of the grading work in the territory. To best supply this information the supervisor should take care that his reports of inspections are made clear and legible. His personal observations of irregularities should be written in the space left on the report blank for remarks. All observations should be substantiated by facts acquired by the supervisor. If such facts are not to be had, yet comment is made upon certain irregularities, the supervisor should qualify his remarks accordingly. Special investigations requested by individual creameries should be given attention at the earliest possible date and the results promptly reported to the creamery requesting the investigation and to the chairman of the association. The supervisor should attend all regular meetings of the cream improvement association and be prepared to make a brief report on conditions prevailing in the grading territory. This report should be prepared in advance. Notes should be made on the conditions to be reported at the meeting with the idea of economizing time, yet not omitting any item that should be reported. Attention to the foregoing points relative to reporting on his work should be of material aid to the supervisor in keeping the association and his employers informed relative to the grading work.

THE CREAMERY'S RESPONSIBILITY

A smooth functioning cream improvement association is fundamental for the successful application of a cream quality improvement program embracing the Four Day Plan of cream grading. An organization of that nature is dependent upon the cooperative efforts of its members and their sincerity relative to quality improvement. The readiness of the individual creameries to support the Four Day Plan and, if necessary, to make sacrifices in its interests, will determine the degree of success attained by the program. Cooperation of this nature will not be attained however, unless the creamery management has sufficient foresight to realize that revolutionary achievements will not follow immediately upon the introduction of the grading program.

There are certain preparatory steps to be taken by the creamery prior to the adoption of the Four Day Plan. These preparatory steps are as follows:

LIBRARY

1. Acquaint all employees, buyers, and producers with the nature of the plan, its application, and the reason for its adoption.

2. Supply all cream buyers with four day tags and other accessories, at least a week or ten days prior to the date set for the plan to go into effect, and instruct the buyers relative to their use.

3. Instruct buyers to commence tagging the producers' cream containers a week or ten days previous to the date set for the plan to become effective.

4. Give definite instructions to cream buyers relative to the date they are to commence buying on the grade basis, and emphasize the fact that such instructions are to be followed without exceptions.

5. Place the responsibility of four-day grading at buying stations on the creamery fieldmen and instruct fieldmen to see that the station buyers observe all rules and regulations of the Four Day Plan.

Attention to the foregoing items by the creamery will do much to insure smooth operation of the grading plan from the start and will prevent confusion among the buyers and producers relative to the grading work.

After the Four Day Plan has been introduced in a territory, the creamery must keep a close check on four-day cream purchases and require that such purchases be strictly in accordance with the plan. This checking may be done effectively and with little disturbance to the customary duties of employees if the following suggestions are observed:

1. Creamery fieldmen should be assigned to do the checking of four day cream purchases at the buying stations as a part of their regular duties.

2. One or more members of the creamery clerical staff should be made responsible for the checking of four day tags (sent in by the buyers) against the buying reports, to see that the price paid for the cream was in agreement with its grade.

3. The cream buyer must be held accountable for cream payments that are not in accordance with the prices quoted by the creamery for the different grades of cream. Corrections for such payments should be made by the creamery immediately after the irregularity is discovered. In cases where payments are made in excess of the quoted price for a particular grade of cream, the amount of the over-payment should be deducted from the buyer's commission or wage.

4. The four day tags collected by the buyers, together with the buying reports, should be preserved by the creamery for at least a week after their receipt in order to permit checking at the creamery by the grading supervisor.

5. The creamery manager, or a representative of the creamery with proper authority, should attend all regular meetings of the cream improvement association.

6. Reports on cream purchases in the four day territory should be sent to the cooperative public agency as requested.

Observance by creameries of the foregoing suggestions will do much towards the establishment of the Four Day Plan on a sound basis. It will tend to build confidence among competitors and make possible closer cooperation with respect to cream quality improvement. Such cooperation is essential to the welfare of the butter industry, and will do much toward stabilizing the cream procurement business thereby benefiting cream producers, butter manufacturers, and cream buyers.

EIGHTEENTH ANNUAL REPORT OF THE CREAMERY LICENSE DIVISION

T. H. Binney

Indiana Dairy Statistics

Indiana continues to be one of the leading states in the manufacture of dairy products. A report of the United States Department of Agriculture, Bureau of Agricultural Economics, for 1930, which is the last report available, shows that this state ranks 11th or above in the manufacture of all dairy products, excepting Dry Skim milk. Indiana's rank among the states for 1930 is as follows:

Product	Rank
Butter	10th
Ice Cream	11th
Condensed and Evaporated Milk	7th
Pressed Cheese	4th
Soft Types of Cheese	8th
Concentrated Skim Milk	4th
Condensed Buttermilk	4th
Dry Buttermilk	11th
Dry Skim Milk	18th

Licensed creameries, milk plants, cheese factories, condenseries, etc., report to the Creamery License Division the amount of butter, milk or other dairy products made or sold during the past calendar year, at the time of making application for their new licenses. With this information, together with figures supplied by the United States Department of Agriculture, Bureau of Agricultural Economics, it is possible to compile reliable statistics concerning the total production of licensed manufacturing plants. The following table is a summary of the reports received from licensed plants for the years indicated:

OUTPUT OF LICENSED PLANTS IN INDIANA FOR 1916, 1920, 1924, 1930 AND 1931

	1916	1920	1924	1930	1931
Pounds of Butter	33,026,796	42,577,180	53,462,104	63,248,581	67,991,081
Pounds of Milk	55,059,940	155,950,136	257,417,090	613,005,756	502,079,739
Pounds of Cream	5,799,663	12,224,488	25,219,252	29,892,859	70,230,197
Gallons of Ice Cream	2,111,701	4,132,318	4,865,465	4,664,131	3,932,034
Pounds of Cheese	82,667	233,806	574,686	11,956,315	14,703,669
Pounds of Sweetened Condensed Milk	1,619,880	6,920,592	8,735,498	2,557,973	1,418,904
Pounds of Evaporated Milk	13,657,248	10,265,791	23,912,054	50,602,364	38,521,763
Pounds of Bulk Evaporated Milk	2,774,880	5,977,716	19,065,245	43,054,573	32,886,766

By comparing the figures for 1931 with those for 1930 in the above table, it will be noted that most of the manufactured products show a decrease. The increase in the amount of butter made is 4,742,500 pounds, or 7.6 per cent. A total of 502,079,739 pounds of milk and 70,230,197 pounds of sweet cream were sold in licensed plants during the past year. This represents a decrease of 18.0 per cent of milk and an increase of 134.9 per cent of cream in 1931 as compared with 1930. The amount of ice cream manufactured during the past year shows a decrease of 732,097 gallons or 15.6 per cent. Cheese production increased 2,747,354 pounds or 22.9 per cent. Sweetened condensed milk decreased 1,139,069 pounds or 44.1 per cent, evaporated milk (case goods) decreased 12,080,601 pounds or 23.8 per cent and bulk evaporated milk decreased 10,167,807 pounds or 23.6 per cent.

In addition to the above products, dairy plants of the state manufactured 14,313,817 pounds of condensed skim milk; 1,651,875 pounds of evaporated skim milk; 9,620,248 pounds of concentrated skim milk (for animal feed); 4,307,068 pounds of condensed or evaporated buttermilk; 4,090,784 pounds of dried or powdered skim milk and 1,986,422 pounds of dried or powdered buttermilk.

An estimate of the total amount of dairy products manufactured in the state may be secured by using the above statistics and estimating the amount of dairy products manufactured and sold in the plants which are not licensed. A large number of ice cream plants and market milk plants buy milk on a gallon or weight basis rather than on a butterfat basis and do not come under the jurisdiction of the Creamery License Division.

AMOUNT OF BUTTER, MILK, ICE CREAM, CONDENSED MILK AND CHEESE

Estimated as Produced in Indiana During 1931

Pounds of Creamery Butter	67,991,081
Pounds of Dairy Butter	10,122,844
Pounds of Milk Consumed	1,583,592,571
Gallons of Ice Cream	8,722,358
Pounds of Condensed and Evaporated Milk	72,827,433
Pounds of Cheese	14,703,669
Pounds of Cottage Cheese	3,716,261

By taking the amount of milk used in the manufacture of each of the various dairy products the total milk production of the state may be calculated. In making this calculation, it has been necessary to estimate the amount of milk and cream consumed direct, the amount of dairy butter made, the amount of milk fed to calves, and the amount of milk lost on farms and in factories.

TOTAL (ESTIMATED) MILK PRODUCTION

Creamery butter used	1,427,812,701	pounds
Dairy butter used	212,579,724	pounds
Milk consumed direct	1,583,592,571	pounds
Ice cream used	119,932,424	pounds
Cheese used	147,036,690	pounds
Condensed milk used	182,068,582	pounds
Milk fed to calves	106,424,200	pounds
Milk shipped out of state	272,627,314	pounds
Losses on farms and in factories	121,562,226	pounds
Total	4,173,636,432	pounds
Milk shipped in	207,965,234	pounds
Total milk production in Indiana	3,965,671,198	pounds

Creamery Licenses

Creamery licenses must be secured by all firms buying and paying for milk or cream on a butterfat basis. Licenses are valid for a period of one year unless revoked for a violation of the Creamery and Testers' License Law or the Rules and Regulations of the Purdue University Agricultural Experiment Station.

During the past year 1,829 creamery licenses were issued. This is a decrease of 64 from the previous year's total of 1,893. Plant licenses show a gain of 3 in number while the number of station licenses show a decrease of sixty-seven.

The following table is a summary of the number and kinds of plants issued creamery licenses during the year ending March 31, 1932, and for previous years as indicated.

CREAMERY LICENSES ISSUED FROM 1925-1931, INCLUSIVE

PLANTS AND STATIONS	NUMBER AND YEAR						
	1925	1926	1927	1928	1929	1930	1931
Butter	51	64	58	56	58	56	58
Milk	78	91	108	129	141	162	147
Ice Cream	14	17	15	11	16	18	16
Cheese	3	3	9	18	17	18	19
Condensed Milk	4	7	8	8	9	8	10
Butter and Milk	31	33	43	39	33	36	46
Butter and Ice Cream	16	12	14	17	13	10	13
Butter and Condensed Milk	1	1	1	0	0	0	0
Butter and Cheese	0	0	0	3	2	1	2
Butter, Milk, and Ice Cream	16	13	16	13	15	20	17
Butter, Milk and Condensed Milk	4	4	4	5	5	7	6
Butter, Milk, Ice Cream and Condensed Milk	6	4	6	7	7	6	6
Butter, Milk, Ice Cream and Cheese	0	0	0	0	0	0	1
Butter, Milk, Cheese and Condensed Milk	0	0	0	0	1	0	0
Milk and Ice Cream	13	19	20	24	18	19	26
Milk and Condensed Milk	4	3	3	2	5	4	5
Milk, Ice Cream and Condensed Milk	2	1	2	2	3	2	0
Milk, Ice Cream and Cheese	0	0	0	0	1	1	0
Total number of Plants	243	272	307	334	344	369	372
Stations	1,618	1,631	1,653	1,614	1,588	1,524	1,457
Total Licensed Issued	1,861	1,903	1,960	1,948	1,932	1,893	1,829

The following table shows the number of plants which reported each of the five major products handled in licensed plants for the years indicated:

PRODUCT	NUMBER OF PLANTS REPORTING						
	1925	1926	1927	1928	1929	1930	1931
Butter	125	131	142	140	134	136	149
Milk	154	168	202	221	229	257	254
Ice Cream	67	66	73	74	73	76	79
Cheese	3	3	9	21	21	20	22
Condensed Milk	21	20	24	24	30	28	31

The accompanying map shows the distribution of plants and stations in the state. The larger circle containing a number is the number of licensed plants operating in each town, while each small circle represents a cream station.

Testers' Licenses and Examinations

In order to secure a license to test a candidate must satisfactorily answer twenty questions on testing in writing, and demonstrate his ability to sample, test and make correct readings of butterfat percentages of both milk and cream. The questions asked a candidate pertain to the testing of milk and cream. All answers are to be found in Circular 41 issued by the Purdue University Agricultural Experiment Station which is sent to the candidate to study before appearing for the examination.

March 1932

Location of Licensed Plants and Stations for Year Ending March 31, 1932.

Five hundred and one candidates appeared for the testers' examination during the past year. This is the smallest number of candidates to take the examination in any year since 1916. The average grade of all candidates was 83%, which is considerably higher than any previous average. This, in addition to the fact that the percentage of failures was much less than for any previous year, would indicate that candidates are better prepared when they appear for an examination.

Twenty-three hundred and fifteen testers' licenses were issued during the past year; a decrease of 80 from the previous year's total of twenty-three hundred and ninety-five.

The following table shows the number of candidates examined and testers' licenses issued for the year indicated:

NUMBER OF CANDIDATES EXAMINED AND TESTERS' LICENSES ISSUED FOR THE YEARS ENDING MARCH 31, 1920, 1924, 1928, 1931 AND 1932

	1920	1924	1928	1931	1932
Number of Individual Examinations	1,339	850	904	518	501
Number of Failures	226	125	290	79	33
Number of Persons Passing Examination	1,113	725	614	439	468
Number of Testers' Licenses Issued	2,371	2,518	2,661	2,395	2,315

The results of the seventy examinations which were held at the nine examination points in the state are given in the following table:

RESULTS OF TESTERS' EXAMINATIONS 1931-1932

PLACE OF EXAMINATION	Number of Examinations	Number of Candidates	AVERAGE GRADES (PER CENT)		
			All Candidates	Candidates Passed	Candidates Failed
Lafayette	15	144	82.6	84.2	60.6
Muncie	6	65	82.2	83.1	69.5
Fort Wayne	9	95	84.0	84.6	70.0
New Albany	4	22	79.2	83.2	53.7
Evansville	8	51	82.6	83.4	69.7
Terre Haute	8	30	85.1	87.1	67.0
Indianapolis	8	39	83.0	83.9	50.0
North Vernon	6	55	84.5	85.5	74.8
Totals	64	501	83.0	84.3	65.4

Glassware Inspection

All glassware used in Indiana, with the exception of cream pipettes, must conform to the Indiana Standard as described in Sections 7 and 12, Chapter 340, Indiana Statute, Acts of 1913. (See circular 41.) To insure the accuracy of testing glassware, all pieces must be inspected by the glassware inspector of the Purdue University Agricultural Experiment Station before being used in the state. All pieces found to be correct are marked "S.G.P.," (Standard Glassware Purdue); all pieces found to be incorrect are destroyed.

During the past fiscal year 39,297 pieces of Babcock testing glassware were examined by the Glassware Inspector of the Agricultural Experiment Station. In addition 24 nine-gram weights were inspected and all found to be correct. This is 4,357 pieces of glassware more and 180 nine-gram weights less than were inspected last year.

The following table gives the amount of each kind of glassware inspected, and the number of pieces found to be incorrect:

GLASSWARE INSPECTION

KINDS OF GLASSWARE	Total Number of Pieces	Number Incorrect	Per Cent Incorrect
Cream Test bottles	24,948	46	.188
Milk test bottles	12,396	0	.000
Milk Pipettes	1,953	0	.000
Summary	39,297	46	.116

The per cent of incorrect glassware received during the past year was less than for any year since 1918. This is quite an improvement over the glassware received the previous year, which shows that the percentage of incorrect glassware was greater than for any year since 1921.

Licenses Revoked and Prosecutions

Representatives of the Creamery License Division inspect cream and milk stations and all licensed plants to determine the accuracy of testing and records pertaining to the purchase of milk or cream. Whenever a tester is found doing incorrect testing or manipulating records, whether intentionally or unintentionally, he is first warned that the Creamery and Testers' License Law is being violated and a continuation of such practices may result in the revocation of his testers' license. If the operator continues to violate the law, evidence is presented to the State Creamery Examining Board for their consideration. The Board recommends to the Purdue Agricultural Experiment Station what action should be taken.

During the past year nine testers were summoned before the Board and in each instance the Board recommended that their Testers' License be revoked.

Mrs. Mattie D. Trotter, Hope, Bartholomew County, Indiana; tester for Columbus Creamery Company, Columbus, Indiana.

Mr. Marshall G. Harman, Warsaw, Kosciusko County, Indiana; tester for George Freese's Sons, Nappanee, Indiana.

Mrs. Leora A. Gray, Ewing, Jackson County, Indiana; tester for Fairmont Creamery Company, Columbus, Ohio.

Mrs. Evelyn Wooley, Columbus, Bartholomew County, Indiana; tester for Farmers Marketing Company, Columbus, Indiana.

Mrs. Genevieve Brooks, Scottsburg, Scott County, Indiana; tester for an Independent Station operated by Tyra Brooks.

Mrs. Fern Reeve, Connersville, Fayette County, Indiana; tester for The Wadley Company, Indianapolis, Indiana.

Mrs. Mary A. Nichols, Freedom, Owen County, Indiana; tester for Johnson Creamery Company, Bloomington, Indiana.

Mrs. Ida Moore, Liberty, Union County, Indiana; tester for Sherman White and Company, Fort Wayne, Indiana.

Miss Mary Robinson, Decatur, Adams County, Indiana; tester for White Mountain Dairy Company, New Bremen, Ohio.

Only one prosecution was made during the year. The company prosecuted paid a fine of $25.00 and $12.15 costs.

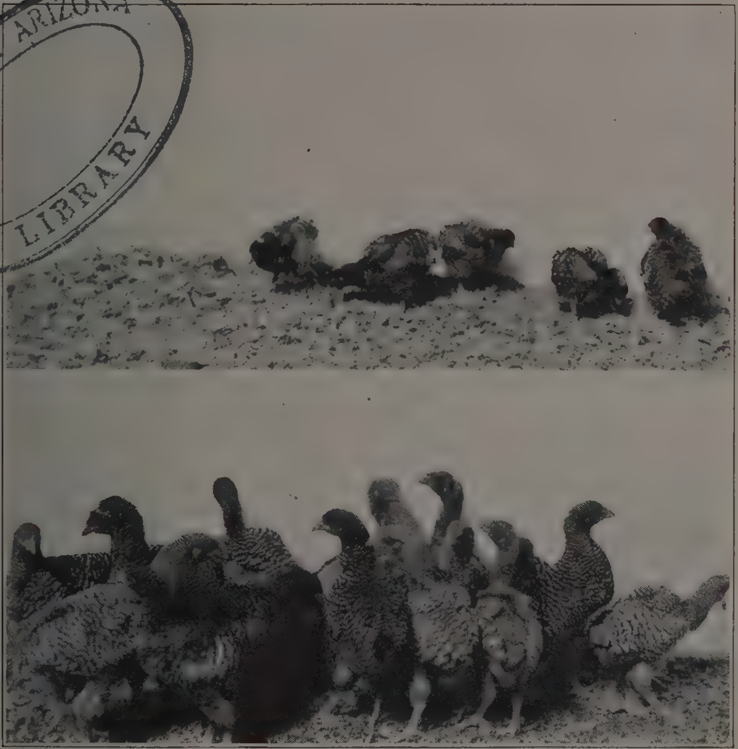
UNIVERSITY OF ARIZONA LIBRARY

Circular No. 195 March, 1933

COMMERCIAL FEEDING STUFFS

SITY OF ARIZONA
LIBRARY



Both groups of chicks were fed alike. Ration of upper group lacked calcium and phosphorus while that of lower group contained an adequate amount of these minerals. However, too large amounts of them may cause "slipped-tendon" (leg deformities). See Table 1 for amount of calcium and phosphorus in feeding stuffs.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular contains a condensed report of commercial feed inspection in Indiana for the year 1932.

From the sale of tags it is estimated that 244,909 tons of commercial feeding stuffs with a retail value of $6,853,043 were sold in Indiana in 1932. The inspectors of the State Chemist Department secured 2,312 samples, or approximately one sample for each 106 tons of feed sold in this state.

Of the 2,312 samples collected 353 were found to be incorrectly guaranteed and 228 were classed as being seriously deficient or misbranded. Shipments not tagged or seriously deficient were withdrawn from sale and manufacturers relabeled such feeds correctly and made refunds to the agents and consumers.

Amendment of the State Feeding Stuffs Law.

Explanation of terms used in the analysis of feeds.

Table 1—Calcium and phosphorus content of feeding stuffs.

Table 2—Average analyses of the common cereals and by-product feeds.

Definitions of feeding stuffs.

Table 3—Summary of withdrawals from sale.

Table 4—Estimated sales of various classes of feeding stuffs.

Table 5—Summary of the annual tonnage and expenditures for commercial feeding stuffs since 1911.

Table 6—Summary of inspection giving the standing of each feed manufacturer.

COMMERCIAL FEEDING STUFFS

H. R. KRAYBILL, *State Chemist*

O. S. ROBERTS, P. B. CURTIS, C. C. YUND, G. E. HALLIDAY, D. M. DOTY

The Indiana Feeding Stuffs Law passed in 1907 and amended in 1909 and in 1933 requires that all commercial feed sold or offered for sale in Indiana be labeled correctly. The intent of the law is to have the manufacturers state on these labels minimum guarantees for crude protein and crude fat, a maximum guarantee for crude fiber and the specific name of each ingredient used in preparing the feed. Mineral feeds containing no organic ingredient do not require the usual chemical feed guarantee but do require a declaration of each ingredient contained therein and the minimum percentages of lime (CaO), phosphoric acid (P_2O_5), iodine (I) and the maximum percentage of salt ($NaCl$) if same are present. With this information the purchaser is able to make an intelligent and economical purchase. The law does not, however, prohibit the sale of properly tagged inferior feeds unless they are actually injurious to livestock or poultry. Copies of this law may be secured by making application to the State Chemist.

To determine the correctness of the feed manufacturer's guarantees, 2,312 samples of commercial feeding stuffs were collected from manufacturers, dealers and consumers in various parts of the state during the year 1932. One inspection sample was secured from approximately each 106 tons of commercial feed sold in Indiana. All of the 2,312 samples were examined microscopically and 2,108 of them were analyzed chemically for moisture, crude protein, crude fat, crude fiber and ash content. Individual reports of analysis were sent to the manufacturer as soon as completed and to the dealer and consumer ten days later.

The year's inspection shows that 85 per cent of the samples were equal to or better than the guarantee of the manufacturer. This percentage is identical with that found for the year 1931. Of the 353 samples incorrectly guaranteed, 228 of them were classed as being seriously deficient or misbranded and not sold in accordance with the Indiana Feeding Stuffs Law.

Shipments found to be seriously deficient were removed from sale immediately and the manufacturers either replaced the shipments with feed up to guarantee or relabeled them with correct guarantees. Where deficient feed had already been sold, refunds were made to the dealers and consumers. The sum of $536.77 was refunded on 53 shipments by 31 different feed manufacturers.

During the year 1932, upon the advice of the State Chemist, 387.0 tons of feeding stuffs representing 161 shipments were withdrawn from sale on account of non-tagging, deficiency, misbranding and other reasons (Table 3). Of this amount 189.5 tons, representing 121 shipments, were removed because of lack of Indiana state tags.

Amendment of Feeding Stuffs Law

The Indiana Feeding Stuffs Law was amended through passage of House Bill No. 31, which was approved by the Governor March 8, 1933 (Chapter 179, The Acts of 1933) (Emergency).

The law as amended permits the manufacturer or agent desiring to sell any concentrated commercial feeding stuff in packages of five pounds or less to register such feeding stuff in either of two ways, as follows:

First method. The manufacturer or agent may continue to register the feeding stuff as provided in the law previously, paying no registration fee but attaching one Indiana state label to each package of feeding stuff.

Second method. The manufacturer or agent may register the feeding stuff and pay an annual registration fee of $20.00 per brand. When this is done it is not necessary for the manufacturer to attach Indiana state labels to the packages of feed of five pounds or less. In case this method of registration is chosen and Indiana state labels are not attached to the packages of five pounds or less, it is necessary for the manufacturer to print on his label certain information required by the feeding stuffs law as follows: (1) The number of net pounds of concentrated commercial feeding stuff in the package; (2) the name, brand name or trade mark under which the concentrated commercial feeding stuff is sold; (3) the name of the manufacturer; (4) the location of the principal office of the manufacturer; (5) the guaranteed analysis stating the minimum percentages of crude fat and crude protein, the maximum percentage of crude fiber and the ingredients from which the concentrated commercial feeding stuff is compounded.

If the feeding stuff is sold in packages of over five pounds it is necessary for the manufacturer or agent to attach one Indiana state tag or label to each package larger than five pounds.

Estimated Sales of Commercial Feeding Stuffs in 1932

Prevailing conditions make the annual statement of estimated sales of commercial feeding stuffs of more than usual interest. Based on the sale of official tags by the State Chemist, it is estimated that 244,909 tons of commercial feed with a retail value of $6,853,043 were sold in Indiana during the year 1932. Compared with the sales of previous years it may be seen from Table 5 that the tonnage sold and expenditures for same were the lowest since 1913. The reduction is no doubt due to the general economic conditions. Compared to the year 1931, the principal increases in tonnage were for animal by-products and corn gluten products. In practically all of the remaining classes of feed the tonnage dropped to much lower levels. A complete list of the tonnage and expenditures of the various classes of feeding stuffs compared to the immediate years preceding is given in Table 4. Even though the year of 1932 has been a trying one for the feed business, it is satisfying to note that in general the quality of the feeding stuffs has been maintained as compared with previous years. Several shipments of tankage were found to be deficient in crude protein or adulterated with hoof meal and a few samples of bone meal were adulterated with ground limestone. A number of shipments of condensed milk products were also found to be deficient in total solids.

Attention, Manufacturers and Dealers!

Manufacturers or distributors should not neglect to attach proper State Chemist tags to each and every bag of feed shipped into Indiana in order to protect their dealers.

Dealers and consumers should not accept any shipments without State Chemist tags or with such tags showing alterations.

Dealers and consumers should familiarize themselves with the Explanation of Terms Used in the Analysis of Feeding Stuffs as well as with the Definitions of Feeding Stuffs which have been adopted officially by the Association of American Feed Control Officials and published herein.

Table 6, "The Summary of Feed Inspection," is worth consideration by those who purchase commercial feeds.

Table 2, entitled "Average Analyses of Cereals and By-Products," may be helpful to those manufacturers who wish to compute safe guarantees for their feed formulas.

Manufacturers of mineral feeds having difficulty in calculating minimum percentage guarantees of lime (CaO) and phosphoric acid (P_2O_5) for their products should consult Table 1, entitled "Calcium and Phosphorus Content of Feeding Stuffs." Poultrymen and others interested in maintaining a definite calcium and phosphorus ratio in their feeds will also find valuable information in this table. Since minimum percentages of calcium expressed as lime (CaO) and phosphorus expressed as phosphoric acid (P_2O_5) are required in the guarantee of mineral feeds these values are stated rather than the actual percentages of calcium and phosphorus. If the percentage of calcium is desired the percentage of lime (CaO) must be multiplied by 0.7. If the percentage of phosphorus is desired the percentage of phosphoric acid (P_2O_5) must be multiplied by 0.44. While the values listed in the table may not be absolute they do represent average values. A study of the cover page reveals the importance of supplying these minerals in adequate amounts to poultry rations.

TABLE 1. CALCIUM AND PHOSPHORUS CONTENT OF FEEDING STUFFS

MATERIAL	Lime (CaO) %	Phosphoric Acid (P_2O_5) %
Alfalfa meal	1.70	0.53
Brewers' dried grains	0.22	1.03
Corn	0.02	0.65
Corn gluten feed	0.35	0.62
Cottonseed meal	0.37	2.89
Cowpeas	0.14	1.02
Distillers' grain corn	0.06	0.67
Linseed oil meal	0.51	1.65
Malt sprouts	0.21	1.61
Meat and bone scraps	14.00	11.55
Oats	0.14	0.85
Skimmed milk dried	1.80	2.20
Soy beans	0.29	1.37
Soy bean oil meal	0.38	1.43
Tankage digester	8.26	6.66

Explanation of Terms Used in the Analysis of Feeding Stuffs

Moisture is the varying quantity of water occurring in feeding stuffs which can be driven off by heat at the temperature of boiling water. The amount of water present varies with the temperature, moisture content of the air, process of manufacture and the character of the substance. In most concentrates this value ranges from 5 to 15 per cent.

Crude Fat consists mainly of fats and oils with small amounts of waxes, resins, coloring matter and similar substances, dissolved from feeding stuffs by dry ether. In calculating the heat and energy value of a feed, the fat is considered 2.25 times greater than that of either carbohydrates or protein.

Crude Protein is the term applied to the nitrogenous constituents of a feeding stuff. It is obtained by multiplying the total nitrogen by 6.25. Protein is the most important as well as the most costly constituent in a feed. Plants have the power of building up protein from the inorganic elements of the soil and air while animals must secure their protein from the plants or other animals. The plant proteins contain varying amounts of the essential amino acids, therefore it is necessary to carefully select a variety of feeds which will furnish the essential amino acids economically.

Crude Fiber is the woody portion of a feeding stuff, for the most part cellulose, and is insoluble in dilute acids and alkalis. Most of the common seeds and grains contain very little fiber while the hulls, husks and stems are high in this constituent. In poultry and swine, crude fiber when present in considerable quantities exerts a retarding influence on the digestion of nutrients present.

Ash, the mineral matter of plants, is the residue left after burning a feeding stuff at low redness. It consists chiefly of the phosphates, sulphates, chlorides and carbonates of sodium, potassium, calcium and magnesium. The calcium and phosphorus are absolutely essential for the proper nutrition of the animal.

Nitrogen Free Extract consists of sugars, starches, pentoses, non-nitrogenous organic acids, etc., and is determined by subtracting the sum of moisture, crude fat, crude protein, crude fiber and ash from 100.

Carbohydrates is the sum of the crude fiber and nitrogen-free extract.

TABLE 2—Average Analysis of Cereals and By-Products

Material	Description of	Pounds in One Hundred		
		Crude Fat	Crude Protein	Crude Fiber
Alfalfa meal	Entire ground hay	1.5	13.0	33.0
Alfalfa leaf meal	Largely alfalfa leaves	2.5	20.0	18.0
Barley	Whole or ground	1.8	11.0	6.0
Beet pulp	Dried	0.9	8.5	18.0
Blood (dried)	Blood meal	0.5	80.0	none
Bone (raw)	Raw bone	3.0	20.0	1.0
Bone (steamed)	Steamed bone	0.5	6.0	1.0
Brewers' dried grains	From manufacture of beer	6.0	26.0	15.0
Buckwheat	Whole or ground	2.2	10.0	10.0
Buckwheat mixed feed	Entire product from manufacture of buckwheat flour	3.2	12.0	28.0
Buckwheat middlings	Entire product from manufacture of buckwheat flour, except the hulls	7.3	28.8	6.4
Buttermilk (dried)	Dried buttermilk	5.0	30.0	none
Buttermilk (condensed)	Condensed buttermilk	2.0	10.0	none
Cane seed	(Sorghum) removed from head and cleaned	2.5	9.0	2.5
Charcoal	Charcoal	none	none	90.0
Cob meal	Ground corn cob	0.5	2.0	31.0
Cocoanut oil meal	Dried cocoanut meats with partial extraction of oil	8.0	22.0	9.0
Corn	Old corn No. 2	4.0	9.5	2.0
Corn and cob meal	Ear corn (old)	3.5	8.0	8.0
Corn bran	Containing little corn germ	2.5	7.0	10.0
Corn mill feed	Corn bran germ and some meal from manufacture of meal or corn flour	7.4	11.0	4.2
Corn feed meal	Manufacture of cracked corn	3.5	9.0	2.0
Corn germ oil meal	Corn germ with part of the oil removed	8.0	20.0	8.0
Corn gluten feed	Remains after the larger part of starch and germ is removed	2.0	25.0	7.0
Corn gluten meal	From manufacture of corn starch and glucose	1.0	42.0	2.0
Corn screenings	Small and broken grains of corn, small pieces cob, etc., removed from shelled corn	2.7	8.6	8.6
Cottonseed meal (prime quality)	Sold as 36 per cent protein	6.0	36.0	14.0
Cottonseed meal (prime quality)	Sold as 41 per cent protein	6.0	41.0	12.0
Cottonseed meal (prime quality)	Sold as 43 per cent protein	6.0	43.0	10.0
Cottonseed feed	Below 36 per cent protein	4.0	22.8	22.0
Cottonseed hulls	Contains trace of lint and meal adhering	1.8	4.6	38.0
Cowpea	Seeds, pods removed	1.4	20.8	4.1
Distillers' grain (dried)	From corn or rye	9.0	27.0	12.0
Emmer	Often called spelt	2.0	11.5	10.0
Fish meal	Dried ground tissues of fish with or without the extraction of part of the oil	6.0	55.0	2.0
Flaxseed	Whole grain or meal without extraction of oil	32.0	22.0	7.0
Flax plant by-product	Shives, pods, etc.	2.1	15.0	31.0
Flaxseed screenings	Small and broken grains, flaxseed, weed seed and other foreign material cleaned from flaxseed	8.0	14.0	14.0
Hominy feed, meal or chop	Manufacture of hominy grits or meal by degerminator process	6.0	11.0	6.0
Kaffir corn	Milo	2.5	10.0	2.5
Kelp (dried)	Ground dried kelp	1.0	6.0	10.0
Linseed meal (old process)	Oil extracted by pressure	6.0	34.0	8.0
Malt sprouts	Sprout of the barley grain	1.3	27.9	12.1

Meat scraps	Ground dry rendered residue from animal tissues	6.0	50.0	3.0
Millet	Italian millet seed	3.9	10.3	9.4
Milo	Whole or ground	2.5	10.7	2.5
Molasses	From beets	none	3.0	....
Molasses	Blackstrap from cane	none	3.0	....
Oats	Ground or whole	4.0	11.0	11.0
Oat-clipped by-product	Clippings	2.0	9.0	30.0
Oat-groats	Kernels of oat berry	6.5	15.0	2.0
Oat hulls	Oat hulls	1.5	4.0	32.0
Oat meal mill by-product	Oat hulls and oat shorts	1.5	6.0	28.0
Oat middlings	Floury portion of oat groat	5.0	15.0	5.0
Peanut oil feed	Peanut meats and peanut hulls	6.0	30.0	25.0
Peanut oil meal	Residue after the extraction of part of the oil from peanut kernels	6.0	40.0	6.0
Peanut shells	Whole or finely ground	1.2	5.5	70.9
Rice bran	Cuticle layer beneath hull	12.0	12.0	12.0
Rye	Rye	1.5	11.0	2.0
Rye feed	Rye feed	3.5	16.0	5.0
Skimmed milk (dried)	Dried skimmed milk	0.5	30.0	none
Soybean	Seed pods removed	19.0	35.0	5.0
Soybean oil meal	Ground	6.0	40.0	6.0
Sunflower seed	Whole or ground	19.0	16.0	30.0
Tankage (digester)	60 per cent reinforced with concentrated tank water or dried blood	6.0	60.0	3.0
Unscreened flaxseed oil feed	Flaxseed meal and flaxseed screenings	6.0	30.0	9.0
Velvet bean feed	Velvet beans and pods	4.0	19.0	17.0
Wheat	Whole or ground	1.9	11.9	2.4
Wheat bran (soft)	Wheat bran	3.5	14.5	8.0
Wheat bran (hard)	Wheat bran	4.0	16.0	10.0
Wheat middlings	Wheat middlings	3.5	15.5	6.0
Wheat standard middlings	With and without screenings	4.0	16.0	9.5
Wheat red dog flour	Red dog flour	3.5	15.0	4.0
Wheat mixed feed and mill run screenings	Bran, middlings, red dog flour and screenings	3.5	15.0	8.0
Whey (dried)	Dried whey	0.5	12.0	none

DEFINITIONS OF FEEDING STUFFS*

ALFALFA PRODUCTS

Chopped Alfalfa is the entire alfalfa hay, chopped and not ground finely enough to become a meal. It must not contain an admixture of alfalfa straw or other foreign material. (Adopted prior to 1928.)

Alfalfa Meal is the product obtained from the grinding of the entire alfalfa hay, without the addition of any alfalfa stems, alfalfa straw or foreign material, or the abstraction of leaves. It must be reasonably free from other crop plants and weeds, and must not contain more than 33 per cent crude fiber. (Adopted 1928.)

Alfalfa Leaf Meal is the ground product consisting chiefly of leafy materials separated from alfalfa hay. It must be reasonably free from other crop plants and weeds and must not contain more than 18 per cent crude fiber. (Adopted 1928.)

Alfalfa Stem Meal is the ground product remaining after the separation of the leafy material from alfalfa hay or meal. It must be reasonably free from other crop plants and weeds. (Adopted 1928.)

ANIMAL PRODUCTS

Blood Meal is ground, dried blood. (Adopted 1926.)

Blood Flour is dried blood, prepared by special processes and reduced to a fine powder. (Adopted prior to 1928.)

Digester Tankage, Meat Meal Tankage or Feeding Tankage is the residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry rendering or a mixture of the products made suitable by drying and grinding. When these products contain more than 10 per cent phosphoric acid (expressed as P_2O_5) they shall be designated Digester Tankage with Bone, Meat and Bone Meal Digester Tankage, Meat and Bone Meal Tankage, or Feeding Tankage with Bone. If they bear a name descriptive of their kind, composition or origin they must correspond thereto. (Adopted 1928.)

Meat Scraps is the ground, dry-rendered residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice. When this product contains more than 10 per cent phosphoric acid (expressed as P_2O_5), it shall be designated Meat and Bone Scrap. If it bears a name descriptive of its kind, composition or origin it must correspond thereto. (Adopted 1928.)

Raw Bone Meal is the dried, ground product suitable for animal feeding, obtained by cooking in water at atmospheric pressure, undecomposed bone, just enough to remove excess fat and meat. It must not contain less than 23 per cent protein. (Adopted 1929.)

Steamed Bone Meal is the dried, ground product suitable for animal feeding obtained by cooking bones with steam under presssure. (Adopted 1929.)

Special Steamed Bone Meal is the dried, ground product suitable for animal feeding obtained by cooking dried bone after the removal of grease and meat fiber with steam under pressure in the process of obtaining gelatine or glue. (Adopted 1929.)

BREWERS' AND DISTILLERS' PRODUCTS

Brewers' Dried Grains are the dried residue obtained in the manufacture of beer. (Adopted prior to 1928.)

Distillers' Dried Grains are the dried residue obtained in the manufacture of alcohol and distilled liquors. The product must bear the designation indicating the cereal predominating. (Adopted prior to 1928.)

---

* These definitions have been adopted by the Association of American Feed Control Officials.

Distillers' Corn Solubles is a by-product from the manufacture of alcohol from corn solids obtained by the evaporation of the mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928.)

Distillers' Rye Solubles is a by-product from the manufacture of alcohol from rye solids obtained by the evaporation of mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928.)

Distillers' Corn and Rye Solubles is a by-product from the manufacture of alcohol from corn and rye solids obtained by the evaporation of mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928.)

Malt Sprouts are the sprouts of the barley grain obtained from malted barley. Sprouts derived from any other malted cereal must be designated by the name of that cereal. (Adopted prior to 1928.)

Yeast or Vinegar Dried Grains are the properly dried residue from the mixture of cereals, malt and malt sprouts (sometimes cottonseed meal) obtained in the manufacture of yeast or vinegar, and consists of corn or corn and rye from which most of the starch has been extracted, together with malt added during the manufacturing process to change the starch to sugars, and malt sprouts (sometimes cottonseed meal) added during the manufacturing process to aid in filtering the residue from the wort and serve as a source of food supply for the yeast. (Adopted prior to 1928.)

BUCKWHEAT PRODUCTS

Buckwheat Shorts or Buckwheat Middlings are that portion of the buckwheat grain immediately inside the hull secured after separation from the flour. (Adopted prior to 1928.)

CORN PRODUCTS

Corn Meal (Feeding) is finely ground, unbolted corn. (Adopted prior to 1928.)

Corn Bran is the outer coating of the corn kernel, with little or none of the starchy part or germ. (Adopted 1931.)

Corn Feed Meal is the fine siftings obtained in the manufacture of screened corn chop, screened ground corn or screened cracked corn, with or without its aspiration products added. (Adopted 1931.)

Corn Chop, Ground Corn or Cracked Corn is the entire product made by grinding, cutting or chopping the grains of sound Indian corn, and may be fine, medium or coarse, and must not contain more than 4 per cent foreign material. (Adopted 1931.)

Screened Corn Chop, Screened Ground Corn, or Screened Cracked Corn is the coarse portion of corn chop, ground corn or cracked corn from which most of the fine particles have been removed, and must not contain more than 4 per cent foreign material. (Adopted 1931.)

Corn Grits, Hominy Grits are the fine or medium sized, hard flinty portions of sound Indian corn containing little or none of the bran or germ. (Adopted 1931.)

Ear Corn Chops is corn and cob chopped, without the husk, with no greater proportion of cob than occurs in the ear corn in its natural state. (Adopted prior to 1928.)

Corn Gluten Meal is that part of commercial shelled corn that remains after the separation of the larger part of the starch, the germ and the bran, by the processes employed in the manufacture of corn starch. It may or may not contain corn solubles. (Adopted prior to 1928.)

Corn Gluten Feed is that part of commercial shelled corn that remains after the separation of the larger part of the starch and the germs by the processes employed in the manufacture of corn starch. It may or may not contain corn solubles. (Adopted prior to 1928.)

Maltose Process Corn Gluten Feed is the dried residue from degermed corn, after removal of starch in the manufacture of malt syrup. (Adopted prior to 1928.)

Hominy Feed, Hominy Meal or Hominy Chop is the kiln-dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the white corn kernel obtained in the manufacture of hominy, hominy grits, and corn meal by the degerming process. (Adopted prior to 1928.)

Yellow Hominy Feed, Yellow Hominy Meal or Yellow Hominy Chop is the kiln-dried mixture of the mill run bran coating, the mill run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the yellow corn kernel obtained in the manufacture of yellow hominy grits and yellow corn meal by the degerming process. (Adopted prior to 1928.)

Corn Oil Cake consists of the corn germ from which part of the oil has been pressed and is the product obtained in the wet milling process of manufacture of corn starch, corn syrup, and other corn products. (Adopted prior to 1928.)

Corn Oil Meal is ground corn oil cake. (Adopted prior to 1928.)

Corn Germ Cake consists of corn germ with other parts of the corn kernel from which part of the oil has been pressed, and is the product obtained in the dry milling process of manufacture of corn meal, corn grits, hominy feed, and other corn products. (Adopted prior to 1928.)

Corn Germ Meal is ground corn germ cake. (Adopted prior to 1928.)

Corn Screenings are the small light grains of corn, parts of grains of corn and/or other cereals, and other materials having feeding value, obtained by screening shelled corn, excluding sand, dirt and other similar inert materials. (Adopted 1931.)

COTTONSEED PRODUCTS

Cottonseed Meal is a product of the cottonseed only, composed principally of the kernel with such portion of the hull as is necessary in the manufacture of oil; provided that nothing shall be recognized as cottonseed meal that does not conform to the foregoing definition and that does not contain at least 36 per cent protein. Cottonseed meal shall be graded and classed as follows: (Adopted prior to 1928.)

1. **Cottonseed Meal, Prime Quality.** Cottonseed meal, prime quality, must be finely ground, not necessarily bolted, of sweet odor, reasonably bright in color, yellowish, not brown or reddish, free from excessive lint, and shall contain not less than 36 per cent protein. It must be designated and sold according to its protein content. Cottonseed meal with 36 per cent protein must be termed "36 Per Cent Protein Cottonseed Meal, Prime Quality," and higher grades similarly designated (as "43 Per Cent Protein Cottonseed Meal, Prime Quality"), etc. (Adopted prior to 1928.)

2. **Cottonseed Meal, Off Quality.** Cottonseed meal not fulfilling the above requirements as to color, odor and texture must be graded "36 Per Cent Protein Cottonseed Meal, Off Quality," and higher grades similarly designated. (Adopted prior to 1928.)

Cottonseed Feed is a mixture of cottonseed meal and cottonseed hulls, containing less than 36 per cent protein. (Adopted prior to 1928.)

Cold Pressed Cottonseed is the product obtained from the subjection of the whole undecorticated cottonseed to the cold pressure process for the extraction of oil and includes the entire cottonseed less the oil extracted. (Adopted prior to 1928.)

Ground Cold Pressed Cottonseed is the product obtained by grinding cold pressed cottonseed. (Adopted prior to 1928.)

Whole Pressed Cottonseed, prime quality, is the product resulting from subjecting the whole, sound, mature, clean undecorticated cottonseed to pressure for the extraction of oil, and includes the entire cottonseed less the oil extracted and the lint removed. It must be designated and sold according to its protein content. (Adopted 1932.)

Ground Whole Pressed Cottonseed, prime quality, is whole pressed cottonseed, ground. It must be designated and sold according to its protein content. (Adopted 1932.)

LINSEED AND FLAX PRODUCTS

Linseed Cake or Meal is oil cake or meal made from flaxseed. The final product must contain less than 6 per cent weed seeds and other foreign materials and no portion of the stated 6 per cent weed seeds and other foreign materials shall be intentionally added. (Adopted prior to 1928.)

Old Process Oil Meal, Old Process Linseed Meal is oil meal as defined below, produced by crushing, cooking and hydraulic pressure. (Adopted prior to 1928.)

New Process Oil Meal, New Process Linseed Meal is oil meal as defined below, produced by crushing, heating and the use of solvents. (Adopted prior to 1928.)

Flax Plant By-Product is that portion of the flax plant remaining after the separation of the seed, the bast fiber and a portion of the shives, and consist of flax shives, flax pods, broken and immature flax seeds, and the cortical tissues of the stem. (Adopted prior to 1928.)

Ground Flaxseed or Flaxseed Meal is the product obtained by grinding flaxseed which has been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process; the final product must contain less than 4 per cent weed seeds and other foreign materials, and no portion of the stated 4 per cent weed seeds and other foreign materials shall be intentionally added. (Adopted prior to 1928.)

Unscreened Flaxseed Oil Feed Cake is the product obtained by extraction of part of the oil from unscreened flaxseed by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents. The ingredients must be stated as "partially extracted flaxseed and foreign seeds (wheat, wild buckwheat, pigeon grass, wild mustard, etc.)." (Adopted prior to 1928.)

Ground Unscreened Flaxseed Oil Feed is the ground unscreened flaxseed oil feed cake. (Adopted prior to 1928.)

Screenings Oil Feed is the ground product obtained after extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents from the smaller imperfect flaxseed, weed seeds and other foreign materials, having feeding value, separated in cleaning flaxseed. The name of the grain from which the screenings are separated must be prefixed to "screenings oil feed." (Adopted prior to 1928.)

Oil Cake is the product obtained after the extraction of part of the oil by crushing, cooking, and hydraulic pressure, or by crushing, heating and the use of solvents, from flaxseed which have been screened and cleaned of weed seeds, and other foreign materials by the most improved commercial process. When used alone the term "Oil Cake" shall be understood to designate linseed cake as defined. When used to cover any other products the name of the seed from which it is obtained must be prefixed to the words "Oil Cake." (Adopted prior to 1928.)

Oil Meal or Ground Oil Cake is oil cake ground to a meal. (Adopted prior to 1928.)

MILK PRODUCTS

Dried Buttermilk (Feeding) is the product resulting from the removal of water from clean, sound buttermilk derived from natural cream, to which no foreign substances have been added, excepting such as are necessary and permitted in the manufacture of butter. It contains not more than 8 per cent moisture, not more than 13 per cent mineral matter (ash), and not less than 5 per cent butterfat, as determined by the Rose-Gottlieb method. (Adopted 1932.)

Evaporated Buttermilk (Feeding), **Concentrated Buttermilk** (Feeding), **Condensed Buttermilk** (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added excepting such as are permitted and necessary in the manufacture of butter. It contains not less than 27 per cent total solids, not less than 2 per cent butterfat, and not more than .14 per cent ash for each per cent of solids. This definition does not prohibit the use of a distinctive trade name, provided it is followed by one of the names given. (Adopted prior to 1928.)

Dried Skimmed Milk (Feeding) is the product resulting from the removal of water from clean, sound skimmed milk. It contains not more than 8 per cent moisture. (Adopted 1930.)

Dried Soured Skimmed Milk (Feeding) is the product resulting from the removal of water from clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not more than 8 per cent moisture. (Adopted 1932.)

Evaporated Soured Skimmed Milk (Feeding), **Concentrated Soured Skimmed Milk** (Feeding), **Condensed Soured Skimmed Milk** (Feeding) is the product resulting from the removal of a considerable portion of water from the clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not less than 27 per cent total solids. (Adopted 1932.)

Condensed Skimmed Milk (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound skimmed milk. It contains not less than 27 per cent total solids. (Adopted 1930.)

Milk Sugar Feed, Dried Whey (Feeding) is the by-product from the manufacture of cheese and should contain at least 70 per cent lactose (milk sugar). (Adopted 1932.)

OAT PRODUCTS

Oat Hulls are the outer coverings of the oat. (Adopted prior to 1928.)

Oat Middlings are the floury portions of the oat groat obtained in the milling of rolled oats. (Adopted prior to 1928.)

Oat Shorts are the covering of the oat grain lying immediately inside the hull, being a fuzzy material carrying with it considerable portions of the fine floury part of the groat obtained in the milling of rolled oats. (Adopted prior to 1928.)

Oat Chop, Ground Oats, Pulverized Oats, Crushed Oats and Crimped Oats consists of the entire product made by chopping, cutting, grinding, crushing or crimping whole oats. (Adopted 1931.)

Oat Groats are the kernels produced from cleaned and dried oats in the process of manufacturing oat meal. (Adopted 1931.)

Hulled Oats, Undried Oat Groats are the kernels produced from the undried grain in the process of hulling oats. (Adopted 1931.)

Oat Meal, Ground Oat Groats is the product produced by cutting, cracking or grinding oat groats. (Adopted 1931.)

Rolled Oat Groats (Rolled Oats) is the product obtained in the process of rolling oat groats. (Adopted 1931.)

Clipped Oat By-Products is the by-product obtained in the manufacture of clipped oats. It may contain the light chaffy material broken from the end of the hulls, empty hulls, light immature oats and dust. It must not contain an excessive amount of oat hulls. (Adopted prior to 1928.)

Oat Mill Feed (Oat Hulls, Oat Shorts and Oat Middlings) is the entire by-product produced in the manufacture of oat groats and consists of oat hulls, oat shorts and oat middlings. If used in a mixed feed, it shall be called Oat Mill Feed (Oat Hulls, Oat Shorts and Oat Middlings). (Adopted 1932.)

WHEAT PRODUCTS

Wheat Bran is the coarse outer covering of the wheat kernel as separated from cleaned and scoured wheat in the usual process of commercial milling. (Adopted prior to 1928.)

Standard Middlings consists mostly of fine particles of bran, germ, and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and must not contain more than 9.5 per cent crude fiber. (Adopted prior to 1928.)

Flour Middlings shall consist of standard middlings and red dog flour combined in the proportions obtained in the usual process of milling and must not contain more than 6.0 per cent crude fiber. (Adopted prior to 1928.)

Wheat Red Dog is a by-product obtained in the usual commercial process of flour milling, consisting principally of aleurone with small quantities of flour and fine bran particles and must not contain more than 4.0 per cent crude fiber. (Adopted prior to 1928.)

Wheat Low Grade Feed Flour is a by-product obtained in the usual commercial process of flour milling, consisting principally of flour with small quantities of aleurone and fine bran particles and must not contain more than 1.5 per cent crude fiber. (Adopted prior to 1928.)

Wheat Bran and Standard Middlings consists of the two commodities as defined above, mixed in the proportions obtained in the usual process of commercial milling. (Adopted prior to 1928.)

Hard Wheat Mixed Feed (mill-run wheat feed) consists of pure wheat bran and flour middlings combined in the proportions obtained in the usual process of commercial milling. This product must not contain more than 9.5 per cent crude fiber. (Adopted prior to 1928.)

Brown Shorts (Red Shorts) consists mostly of the fine particles of bran, germ and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and must not contain more than 7.5 per cent crude fiber. (Adopted prior to 1928.)

Gray Shorts (Gray Middlings or Total Shorts) consists of the fine particles of the outer bran, the inner bran or bee-wing bran, the germ and the offal or fibrous materials, obtained from the "tail of the mill." This product must be obtained in the usual process of commercial milling and must not contain more than 6.0 per cent crude fiber. (Adopted prior to 1928.)

White Shorts or White Middlings consists of a small portion of the fine bran particles and the germ and a large portion of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual process of flour milling and must not contain more than 3.5 per cent crude fiber. (Adopted prior to 1928.)

Wheat Mixed Feed (Mill-run wheat feed) consists of pure wheat bran and the gray or total shorts combined in the proportions obtained in the usual process of commercial milling. This product must not contain more than 8.5 per cent crude fiber. (Adopted prior to 1928.)

Screenings consists of the smaller imperfect grains, weed seeds, and other foreign materials, having feed value, separated in cleaning the grain. (Adopted prior to 1928.)

Scourings consists of such portions of the cuticle, brush, white caps, dust, smut and other materials as are separated from the grain in the usual commercial process of scouring. (Adopted prior to 1928.)

(NOTE) If to any of the wheat or rye by-products feeds there should be added screenings or scourings—as above defined, either ground or unground, bolted or unbolted, such brand shall be so registered, labeled and sold as clearly to indicate this fact. The word "Screenings" or "Scourings" as the case may be, shall appear as part of the name or brand and shall be printed in the same size and face of type as the remainder of the brand name. When the word "Screenings" appears it is not necessary to show also on the labeling the word "Scourings." (Adopted prior to 1928.)

MINERAL FEEDS

Mixed feeds containing both feed and more than 5 per cent of mineral ingredients requires, in addition to the usual declaration of the chemical feed analysis, a declaration of each ingredient contained therein and the minimum percentages of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present. If minerals predominate in the mixture, the usual declaration of the chemical feed analysis, with the exception of protein, may be omitted.

In mineral feeds containing no organic ingredient, the usual chemical feed guarantee need not be made. A declaration should be made of each ingredient contained therein and the minimum percentage of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present.

The mineral ingredients should be stated in the common English terms, if any such terms exist.

It being impossible to classify separately the drug ingredients and the mineral ingredients, be it resolved:

(1) That all mixtures containing mineral ingredients generally regarded as dietary factors essential for the normal nutrition of animals and which are sold or represented for the primary purpose of supplying these minerals as additions to rations in which these same mineral factors may be deficient, be classified as mineral feeds.

(2) That all other preparations which are sold or represented primarily for the cure, mitigation or prevention of disease be classified by this Association as drugs, medicines or specifics. (Adopted prior to 1928.)

TENTATIVE DEFINITIONS

Iodized Salt (feeding) is common salt (NaCl) containing not less than 0.015 per cent iodine, uniformly distributed.

Hominy Feed is a mixture of corn bran, corn germ and a part of the starchy portion of either white or yellow corn kernels or mixture thereof as produced in the manufacture of pearl hominy, hominy grits, or table meal, and shall contain not less than 5 per cent fat. If prefixed with the words "white" or "yellow," the product must correspond thereto.

Hominy Meal is finely ground hominy feed.

Linseed Cake or Meal is oil cake or meal made from flaxseed; provided that the final product must contain less than 6 per cent weed seeds and other foreign materials; and, provided further, that no portion of the stated 6 per cent weed seeds and other foreign materials shall be deliberately added. It shall not contain more than 0.5 per cent acid insoluble ash.

MARINE PRODUCTS

Fish Meal (Feeding) is clean, dried, ground tissues of undecomposed whole fish and/or fish cuttings with or without the extraction of part of the oil, and contains not more than 3 per cent salt (NaCl). If it contains more than 3 per cent salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent.

Fish Residue Meal (Feeding) is the clean, dried, undecomposed residue from the manufacture of glue from non-oily fish, and contains not more than 3 per cent salt (NaCl). If it contains more than 3 per cent salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent.

Crab Meal (Feeding) is prepared from the undecomposed dried waste of the crab industry and contains the shell, viscera and part or all of the flesh. It contains not less than 25 per cent protein and not more than 3 per cent salt (NaCl). If it contains more than 3 per cent salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent.

Shrimp Meal (Feeding) is prepared from the undecomposed dried waste of the shrimp industry and contains the heads, hull and/or the whole shrimp and not more than 3 per cent salt (NaCl). If it contains more than 3 per cent salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent.

Whale Meal (Feeding) is prepared from the clean, dried, undecomposed flesh of the whale, after part of the oil has been extracted. It contains not more than 3 per cent salt (NaCl). If it contains more than 3 per cent salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent.

SOYBEAN PRODUCTS

Ground Soybeans is the product obtained by grinding whole soybeans without cooking or removing any of the oil.

Soybean Oil Cake, Soybean Oil Chips is the product obtained by crushing, cooking and removing part of the oil from soybeans.

Soybean Oil Meal is ground soybean oil cake or ground soybean oil chips.

TABLE 3—Withdrawals from Sale

Number of Shipments Withdrawn from sale	Number of Manufacturers Represented	Reasons for Withdrawal from Sale	Amount Withdrawn Tons
121	83	Not tagged	189.5
13	12	Misbranded	13.4
11	10	Deficient in crude protein	15.5
8	7	Mutilated tags	9.2
5	1	Deficient in total solids	157.8
1	1	Deficient in crude fat	1.2
1	1	Excess crude fiber	0.2
1	1	Adulteration and deficiency in bone phosphate of lime	0.2
161	....	Totals	387.0

TABLE 4—ESTIMATED SALES OF COMMERCIAL FEEDING STUFFS IN INDIANA

KIND OF FEED	Estimated Tons			Estimated Retail Values, Dollars,	
	1930	1931	1932	1931	1932
Alfalfa meal and leaf meal	3,063	3,906	2,906	156,240	85,599

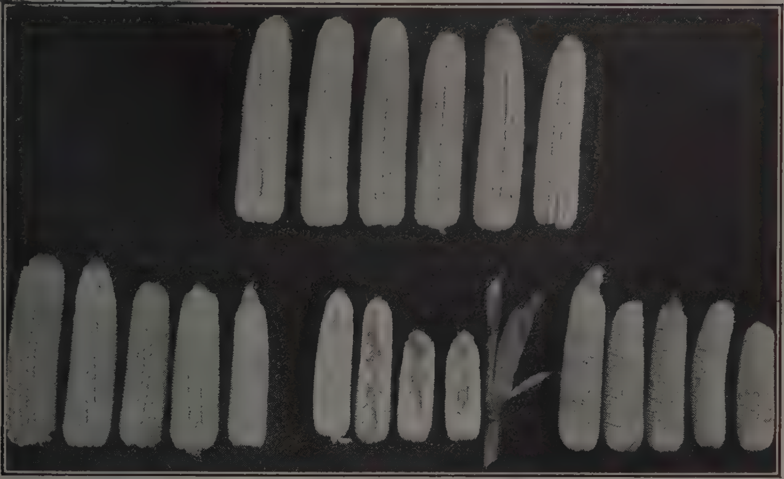
UNIVERSITY OF ARIZONA
LIBRARY

Circular No. 196 May, 1933

COMMERCIAL FERTILIZERS

LIBRARY
UNIVERSITY OF ARIZO



Upper Center—Abundant balanced fertility
Lower left—Nitrogen deficiency
Lower center—Phosphate starvation
Lower right—Potash starvation

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular gives a detailed report of the inspection of commercial fertilizers for the year 1932. The inspectors visited every county in the state in both the fall and spring season and collected 1,138 official samples or one sample for approximately each 90 tons of fertilizer sold.

The Indiana Fertilizer Law protects the honest and efficient manufacturer, dealer and agent as well as the consumer. In order to obtain maximum protection the consumer must read carefully and understand thoroughly the information on the tag.

Refunds amounting to $357.91 were paid by 18 manufacturers on 59 shipments of deficient fertilizer.

There are no satisfactory substitutes for fertilizer (see page 5).

Table 1 gives the average composition of the common fertilizer materials.

Table 3 shows the tonnages of the different analyses which were sold in largest quantities. The tonnage sales of 2-12-6 amounted to over 30 per cent of all fertilizer sold. Over 80 per cent of the total tonnage was confined to 33 analyses while less than 20 per cent was divided among 120 different grades.

The average content of actual plant food in all of the fertilizers sold in 1932 was 458 pounds per ton. The average analysis was ~~2.4~~ 2.3 per cent nitrogen, 12.8 ~~13.6~~ per cent available phosphoric acid and ~~7.1~~ 6.5 per cent water soluble potash.

Table 11 gives the standing of manufacturers as determined by inspection for the year 1932.

Due to lack of funds the table giving the analyses of individual samples is omitted from the report this year. It is intended to resume publication of the table in future publications as soon as funds are available.

COMMERCIAL FERTILIZERS

H. R. KRAYBILL, *State Chemist*

O. S. ROBERTS O. W. FORD L. E. HORAT
M. H. THORNTON

This circular gives the results of the inspection of commercial fertilizers for the year 1932. From the sale of tags it is estimated that 79,400 tons of fertilizer were sold while from manufacturers reports a tonnage of 100,581 is indicated. It is believed that the latter figure represents more nearly the actual tonnage. The difference between the two estimates is doubtless due to the fact that manufacturers reduced their stocks of tags on hand during the year.

Inspectors from the department visited every county in the state in both the fall and spring season and collected 1,138 official samples. Thus one sample was drawn for approximately each 90 tons of fertilizer that were sold. Of these samples 1,053 were equal to or above the guarantee in value; 80 were within 10 per cent of the value guaranteed, and 5 were 10 per cent or more below the guarantee in value. Fourteen of the 816 samples which contained nitrogen contained nitrogen of inferior quality, of which 7 were dried manure and 3 were muck.

The Indiana Fertilizer Law is essentially a correct labeling act. The intent of the law is not to determine what type of fertliizer may be sold. The law is designed to furnish the purchaser with a true statement of certain information on the state tag that will enable him to decide whether or not the fertilizer is the type that will meet his needs. The state tag gives a statement of the percentage of total nitrogen, the total or the available phosphoric acid and the water soluble potash. With this information available the purchaser should be able to judge whether the fertilizer offered for sale meets his requirements. *In order to do this the consumer must read carefully and understand thoroughly the information on the state tag.*

The Indiana Fertilizer Law protects the honest and efficient manufacturer, dealer and agent as well as the consumer. Full cooperation on the part of the manufacturer, dealer, agent and consumer is necessary in order to accomplish the full purpose of the law.

A copy of the full text of the law will be sent to persons making requests for the same to the State Chemist, Purdue University Agricultural Experiment Station, Lafayette, Indiana.

Refunds

Every year a few cases of deficiencies occur due to errors in labeling the fertilizer. This results from carelessness on the part of the person responsible for attaching the tags. Manufacturers should guard against such errors.

When deficiencies in analysis amounting to $1.00 or more per ton on raw materials, as calculated from the wholesale price, are found, refunds are calculated and indicated on the report of the analysis which is sent to the manufacturer and to the consumer. Refunds on mixed fertilizers are usually calculated when one ingredient is deficient to the extent of $1.00 or more per ton regardless of the excess in amounts of the other ingredients. Nitrogen, phosphoric acid and potash play definite roles in crop production. An excess of one ingredient will not necessarily compensate for a deficiency of another.

All refunds are required to be distributed to the consumer wherever possible and receipts for the same must be filed with the State Chemist. In case there are no records as to the consumer the refunds may be turned over to a local charitable organization but receipts for the same must be filed with the State Chemist.

The payment of a refund by the manufacturer to the consumer does not remove the violation but it does indicate good intentions on the part of the manufacturer and shows his willingness to do what he can to correct the violation in so far as possible. However the payment of the refund does not nullify the right of anyone in the state to call a deficiency of analysis to the attention of the prosecuting attorney.

Refunds amounting to $357.91 were paid by 18 manufacturers on 59 shipments of fertilizer in 1932.

Manufacturers

The term "Commercial Fertilizer" is defined by law to include all materials used for manurial purposes except barnyard manure, marl, lime, wood ashes and plaster. Barnyard manure, sheep manure and muck when dried or processed in any way come under the provisions of the law. Before any commercial fertilizer is exposed or offered for sale or sold in the state it is necessary to register the fertilizer with the State Chemist and tag it properly with Indiana State Tags or Labels. Bulk shipments must be accompanied with sufficient labels to cover the total weight of the material.

Manufacturers should not ship fertilizer without having it properly tagged with Indiana state tags. Experiences has shown that when this is done it is difficult to avoid the sale of untagged fertilizer. The State Chemist has no authority to grant permission to a manufacturer to ship unlabeled fertilizer.

Agents, Dealers and Distributors

Agents should familiarize themselves with the provisions of the Indiana Fertilizer Law. Each package of fertilizer offered or exposed for sale or sold in Indiana must have attached to it the Indiana state tag bearing the fac simile signature of the State Chemist (see reproduction page 12). *In case you receive a car of untagged fertilizer wire the manufacturer for tags and notify the State Chemist. Do not accept the shipment until proper tags are furnished.*

Since local agents are responsible for the fertilizer that they offer for sale, they should deal only with those manufacturers who agree to assume full responsibility in cases where the fertilizer fails to meet the requirements of the law.

When inspection reports show that fertilizer in your possession is deficient enough so that a refund is calculated on it, withdraw it from sale at once *and notify the State Chemist giving the date and the amount withdrawn from sale.*

Consumers

The Indiana state tag is your guarantee of the fertilizer that you purchase. Read the tag. Let the analysis on the state tag be your guide rather than the brand name. Refuse to accept any fertilizer which does not have the Indiana state tag attached to each package.

When analysis of a fertilizer is desired do not forward a sample but notify the State Chemist telling how much you have on hand and send in a copy of the official label which is attached to the fertilizer.

Purchase the type of fertilizer that will meet the plant food requirements of your crops. Consult Circular No. 162 of the Purdue University Agricultural Experiment Station entitled "Fertilizers for Indiana Soils and Crops."

Caution

The consumer should remember that the presence of the Indiana state label with the fac simile signature of the State Chemist does not mean that the State Chemist recommends the fertilizer. Poor quality fertilizer may be sold legally provided it is correctly labeled. The consumer should be guided by the analysis of the fertilizer.

The consumer should also beware of products which are not fertilizers but which are sold to take the place of lime or fertilizer. There are no products which are satisfactory substitutes for lime and fertilizer. One such product was submitted for analysis to the State Chemist during the last year. Analysis showed that it contained 0.17 per cent total nitrogen, 0.00 per cent phosphoric acid, and 0.06 per cent of water soluble potash and that it had a neutralizing value equivalent to 11.25 per cent of pure limestone. This product has no more fertilizer value than an equal quantity of a good soil mixed with a small amount of lime, yet it is sold at a price that would be equal to over a million dollars for an acre of soil one half foot deep.

Meaning of Analysis

As recognized under the Indiana Fertilizer Law there are only three valuable fertilizer elements, nitrogen, phosphorus and potassium. These three elements do not occur in a free state but are always combined as chemical compounds. This facilitates the handling of them in commercial fertilizer mixtures. A brief discussion of these, their value and availability as plant food follows:

Nitrogen.—In 1881 when the Indiana Fertilizer Law was passed the principal source of nitrogen was of an organic nature. The nitrogen was derived largely from such products as dried blood, bone, tankage and slaughter house by-products, garbage, tankage, cottonseed meal, castor pomace, tobacco stems, manure sweepings and dried peat. Although there is little water soluble nitrogen in the above products all carry a good source of nitrogen with the exception of garbage tankage, manure sweepings, tobacco stems and dried peat. In more recent years most of the animal products have been diverted into the mixed feed channels and water soluble forms of nitrogen have taken their place in fertilizer mixtures. Today we find that most of the nitrogen carrying fertilizers have more than 80 per cent of their nitrogen content in some water soluble form.

A few of the sources of water soluble forms of nitrogen are as follows: nitrate of soda (natural and synthetic), ammonium sulphate, cal-urea, cal-nitro, urea, cyanamide and calcium nitrate.

Since water soluble forms of nitrogen are considered as being readily available for plant growth, we class a fertilizer that has 60 per cent of its guaranteed nitrogen as water soluble as satisfactory.

If less than 60 per cent of its guaranteed nitrogen is water soluble then the availability of the insoluble organic nitrogen is determined by the alkaline permanganate method. In this case if the active water insoluble nitrogen is equal to or greater than the inactive the nitrogen is classed as satisfactory. If less than half of the insoluble nitrogen is active the nitrogen is classed as inferior.

Manures and garbage tankages that have not been acidulated show an inferior quality of nitrogen. This is not the fault of the manufacturer when they are sold as manure and garbage tankage.

Phosphoric Acid.—The phosphorus in the fertilizer is linked up as chemical compounds with calcium, iron and aluminum. It may be present as mono-, di- or tricalcium phosphate.

As monocalcium phosphate $CaH_4(PO_4)_2$ it is water soluble and readily available to plants for growth.

As dicalcium phosphate $Ca_2H_2(PO_4)_2$ it is soluble in the soil solution and rendered available to plants for growth.

As tricalcium phosphate $Ca_3(PO_4)_2$ it is somewhat less available to plants.

As a complex tricalcium phosphate combined with fluorine and lime (raw rock phosphate) it is much less available to plants and becomes available only slowly in the soil.

The bulk of the fertilizer sold today contains mixtures of large amounts of mono- and dicalcium phosphate and some tricalcium phosphate. This is in contrast to the earlier years when most of the fertilizer used was bone where the phosphorus is present as tricalcium phosphate.

In acidulated goods the phosphorus is sold only on the basis of the available phosphoric acid (P_2O_5) content. The available is the sum of the soluble and reverted phosphoric acid (P_2O_5).

In bone and rock phosphate when sold as such the phosphorus is sold only on the basis of the total phosphoric acid (P_2O_5) content. It is only fair to state, however, that about 60 to 75 per cent of the total phosphoric acid (P_2O_5) content of bone is available by the neutral ammonium citrate method while only from three to six per cent of the total phosphoric acid (P_2O_5) of rock phosphate is available by the same method.

Potash.—Potash, as the official label states, must be soluble in water, in which form it is considered directly available for plant use.

No difference in crop growth has been noted in American, French or German potash. Muriate of potash (KCl) being the cheapest has largely supplanted other potash salts for general crops.

Average Composition of Fertilizer Materials

Table 1 gives the average composition of some of the more common fertilizer materials.

TABLE 1. Average Composition and Comparative Evaluation of the Common Fertilizing Materials

Material	Nitrogen Per Cents							Phosphoric Acid Per Cents			Water Soluble Potash Per Cent	Comparative Value Per Ton Dollars
	Total	Water Soluble Organic	Water Soluble Ammonia	Water Soluble Nitrate	Water Insoluble Organic	Active Insoluble Organic	Inactive Insoluble Organic	Total	Insoluble	Available		
Sodium Nitrate	15.5			15.5								$23.25

*Largely Nitrate of Soda.
†Nitrate of Soda and Ammonium Sulphate.
‡Light Sales.

Many Grades Unnecessary

Table 3 shows the tonnage of fertilizer sold under the different grades of analyses. Over 80 per cent of the tonnage is represented by 33 grades while less than 20 per cent was distributed over 120 analyses. Considerable saving could be made by the manufacturer if the number of grades were reduced materially.

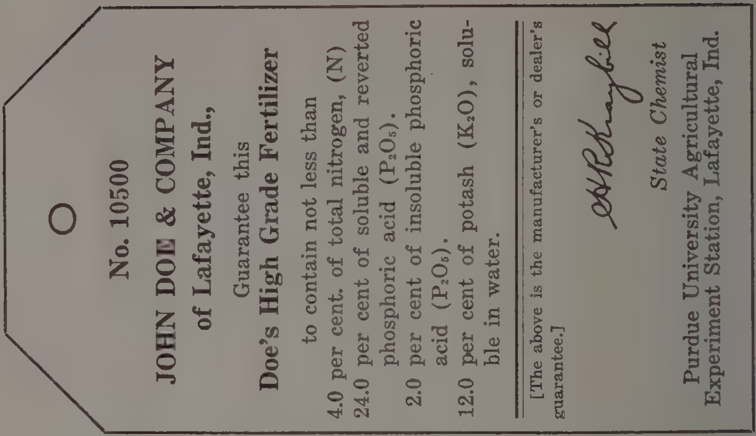
Official State Label



No. 10500

JOHN DOE & COMPANY

of Lafayette, Ind.,

Guarantee this

Doe's High Grade Fertilizer

to contain not less than

4.0 per cent. of total nitrogen, (N)

24.0 per cent of soluble and reverted phosphoric acid (P_2O_5).

2.0 per cent of insoluble phosphoric acid (P_2O_5).

12.0 per cent of potash (K_2O), soluble in water.

[The above is the manufacturer's or dealer's guarantee.]

H R Kraybill

State Chemist

Purdue University Agricultural Experiment Station, Lafayette, Ind.

The only label recognized under the law is that bearing the fac simile signature of the State Chemist. (See reproduction.) The label as issued is always printed and contains all the facts required by law; any alteration thereon constitutes a violation of the law.

Label No. 10500 guarantees that each 100 pounds of fertilizer will contain at least 4.0 pounds of total nitrogen (N), 24.0 pounds of soluble and reverted phosphoric acid (P_2O_5), and 2.0 pounds of insoluble phosphoric acid (P_2O_5), and 12.0 pounds of water soluble potash (K_2O).

We hope that it will not again be necessary to file affidavits against agents for distributing unlabeled fertilizer. There can be no excuse for shipping unlabeled fertilizer. Agents receiving same should protect themselves by refusing to accept the car. Wire the manufacturer for official labels and write the State Chemist fully concerning the unlabeled shipment.

Prices Used in Securing Comparative Value of Fertilizers

These values are not for the purpose of fixing the commercial value of mixed fertilizers, but are for comparative purposes only. They are for use in comparing the value of inspection samples with manufacturers' guarantees, and can be used advantageously by fertilizer purchasers in calculating the relative values of various brands offered for sale by different manufacturers.

For use in determining the comparative values of fertilizer inspected in 1933 the following prices have been adopted:

	Per lb. cts.	Per unit or per cent. $
All fertilizers—		
Nitrogen (N)	7.5	1.50
Potash (K_2O) soluble in water	5.0	1.00
Soluble and reverted phosphoric acid (P_2O_5)	5.0	1.00
Mixed fertilizers containing nitrogen—		
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Precipitated bone—		
Available phpsphoric acid (P_2O_5)	5.0	1.00
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Animal by-products, bone, tankage, etc.—		
Total phosphoric acid (P_2O_5)	3.5	0.70
Basic Slag—		
Total phosphoric acid (P_2O_5)	4.5	0.90
Rock phosphate (floats) and low grade slag—		
Total phosphoric acid (P_2O_5)	1.5	0.30
Mixed fertilizer, acid phosphate, etc., containing no nitrogen—		
Insoluble phosphoric acid	.0	0.00

Table 9 gives the fertilizer tonnage for the spring and fall seasons and also the total tonnage and estimated retail value for the year 1932.

TABLE 9. Fertilizer Tonnage and Estimated Retail Value, 1932

UNIVERSITY OF ARIZONA
LIBRARY

Circular No. 197 June, 1933

REPORT OF
MOSES FELL ANNEX FARM

BEDFORD, INDIANA

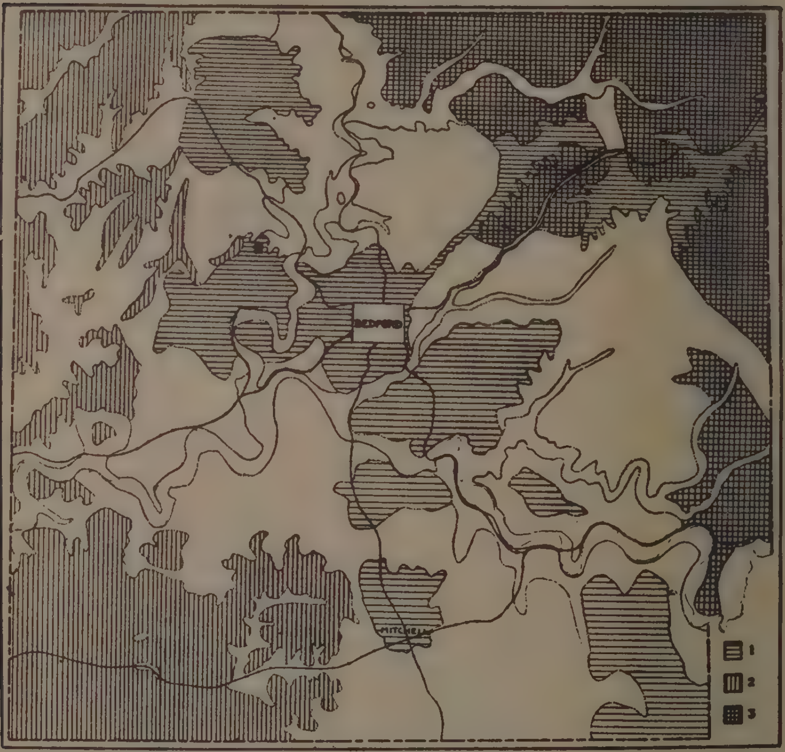
JUNE, 1933

LIBRARY
RSITY OF

The Hon. Moses F. Dunn and Antoinette Fell gave this farm to Purdue University in 1914 so that a long time program of agricultural research and demonstration could be carried forward. It serves the people of southern Indiana without cost to the taxpayers of the State.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

Map Showing Soil Types Similar to Experiment Field



Region	Principal Soil Characteristics
No. 1.	Yellowish limestone land like Bedford experimental field.
No. 2.	Yellowish "freestone" land.
No. 3.	Like No. 1 on ridge tops and like No. 2 on lower slopes.

The results of the Moses Fell Annex Farm can be applied to the greater part of Lawrence County and surrounding territory.

The soil survey made in this county in 1922 enabled the Department of Agronomy to classify the soils of this section and to indicate the types which can benefit most from the experimental work on this farm.

The results will apply to all similar land in the county, which is indicated by shading No. 1 on the map. They will also apply fully as well to the areas indicated by shading No. 2, and more or less fully to the areas indicated by shading No. 3 where the hilltops are like No. 1 and the lower slopes like No. 2.

Portions of the unshaded area would doubtless respond to similar treatments, but most of it does not need either lime or fertilizer to the same extent as the shaded areas.

REPORT OF
MOSES FELL ANNEX FARM

June 1933

H. J. Reed, Farm Director

H. G. Hall, Superintendent

Economical production of farm products and live stock of a satisfactory quality must continue to be an important factor in successful and profitable agriculture.

The work on this farm has shown that the use of the proper fertilizers and high yielding varieties of grain will produce yields that compare favorably with those on the better soils of the state.

The application of these results make possible the further development of the live stock, dairy, and poultry industries in southern Indiana. The limited amount of work on pasture improvement has already shown that a great increase in yield of grass can be obtained by fertilization, and reseeding with a good mixture of adapted grasses. Common and Korean lespedeza are proving worthwhile in old pastures; alfalfa soybeans and clover are successfully produced as hay crops; and sudan grass has been satisfactorily used as supplementing pasture during the hot summer months.

EXPERIMENTAL FACTS POINT THE WAY

These facts suggest the opportunities to go forward in cattle raising, production of poultry and eggs, and dairy products. The flock of Plymouth Rock chickens on this farm demonstrates that a good return can be obtained from a high producing flock.

The work on lamb production has many lessons of value to those interested in sheep and shows that southern Indiana can occupy a more important place in wool and lamb production in Indiana.

Hybrid seed corn grown on this farm produced the highest yield in the yield-test conducted in Ohio last year. Two hundred bushels of potatoes have been produced per acre using complete fertilizer and certified seed. Fifteen hundred to eighteen hundred pounds of tobacco have been produced per acre. Small fruits and canning crops can be successfully grown. A few acres of these intensive crops offer an opportunity for high cash returns on farms with a small acreage of good, tillable land.

The orchard is a practical demonstration of what can be done to produce commercial crops of fruit in this area. Indiana is close to the large consuming centers and can compete successfully with other sections if high quality products are produced economically.

The experimental and demonstration work on this farm can be of practical value to all farmers of this section. The effort is being made to solve problems that will make possible a well balanced program for the further development of southern Indiana Agriculture.

The new gateway erected as a memorial to Moses F. Dunn and Antoinette Fell, commemorating the gift of the Moses Fell Annex Farm to the Purdue University Agricultural Experiment Station for the benefit of the agriculture of southern Indiana.

GENERAL SOIL FERTILITY TEST

The soil fertility experiments carried on under the direction o A. T. Wiancko, Chief, and G. P. Walker, Associate, of the Agronomy Department are showing striking results that are of great value to the farmers o southern Indiana.

The field was laid out and tile drained in the spring of 1917. Th original rotation was corn, wheat, clover and timothy, but this was change in 1923 to corn, soybeans, wheat and clover, which is a more suitable rotation for this kind of land. All crops are removed except on plots 6, 7, 8 10 and 11, where only the ear corn, wheat grain, soybean grain, and clove hay are removed, leaving all the roughage, except the clover hay on the lan in lieu of manure.

The treatments shown in the second column of the table are as follows L = ground limestone; Res. = crop residue; 0 = no treatment; M = manure.

All limed plots received 3 tons of ground limestone per acre in th spring of 1917 and an additional 2 tons in 1931. The fertilizers indicate in the table have been applied at the rate of 200 pounds per acre in the ro for corn and 400 pounds for wheat since 1929. To the end of 1928 the potas in the fertilizer was 4 per cent and the phosphorus and potash were equall divided between the corn and wheat, but the nitrogen was all applied fo wheat, half in the fall and half in the spring.

The manure applications consisted of 6 tons per acre plowed under fo corn in the first round of the rotation. Since then the rate of manurin has been equal to the amount of produce removed during the previous round o the rotation except the wheat grain.

The following table shows the results of different soil treatments begun in 1917:

Table I.--Results of General Fertility Test

Plot No.	Treatment	Average Yields per Acre				Financial Statement per Rotation

NOTE.--In computing the financial results, corn has been valued at 40¢ wheat at 80¢ and soybeans at 80¢ per bushel; and hay at $8.00 per ton Straw and stover have not been counted. Nitrogen has been charged at 7-1/2¢ phosphoric acid at 6¢ and potash at 6¢ per pound. Ground limestone has bee charged at $2.50 per ton. Manure has been charged at 50¢ and residues a $1.00 per ton for spreading on the land.

COMPARE THESE

It will be noted, in comparing with earlier reports and in examining the crops on the experiment field, that the spread between the good and poor treatments is becoming greater year by year, and that the better treatments are becoming more and more profitable. Without soil treatment, the average value of the crops per acre per rotation of corn, soybeans, wheat, and clover, is now $19.48 (plot 14). With lime, manure and fertilizer, the value is $57.63 at an average cost of $9.06 for lime and fertilizer (plot 19).

ONE ACRE CAN DO THE WORK OF TWO

The most profitable returns have been secured on the limed land, which has received an average of 6.8 tons of manure for corn and 450 pounds of superphosphate divided between the corn and wheat in the rotation of corn, soybeans, wheat and clover (plot 18). The crop increases from this treatment have averaged 26.6 bushels of corn; 8.6 bushels of soybeans; 9.8 bushels of wheat; and 1,454 pounds of hay per acre, valued at $37.48 per rotation at a cost of $7.44 for lime and fertilizer.

Phosphorus is by far the most important plant food need of this soil. Applications of superphosphate have been highly profitable, either alone or in addition to manure. Without manure (plot 2) 225 pounds of 16 per cent superphosphate for corn and wheat in the four-year rotation has produced average crop increases of 15.9 bushels of corn, 5.9 bushels of soybeans, 8.3 bushels of wheat and 1,125 pounds of hay per acre, valued at $22.18 at a cost of $4.32 for the fertilizer. On land receiving an average of 6.8 tons of manure for corn, a similar use of superphosphate has further increased the crop yields by 9.9 bushels of corn, 6.1 bushels of soybeans, 7.6 bushels of wheat and 1,181 pounds of hay, valued at $19.67 at a cost of $4.32 for the phosphate, showing that manure is not sufficient on this land. (Compare plots 16 and 18).

In recent years, however, *potash has become increasingly important on the land which has been receiving only phosphate,* showing that the available supply of potash has been so reduced that it has become a limiting factor. It is showing up particularly on the corn and hay. During the last round of the rotation corn has *averaged 10.4 bushels more* and hay 285 pounds more on plot 3 than on plot 2.

Manure applied at an average rate of 5.0 tons per acre for the corn has produced average crop increases of 16.3 bushels of corn, 2.2 bushels of soybeans, 2.4 bushels of wheat and 449 pounds of mixed hay per acre, valued at $11.98, which amounts to an average return of $2.40 per ton of manure applied. (Compare plots 14 and 15).

Ground limestone applied at the rate of three tons per acre in 1917 and 2 tons in 1931 has so far produced average crop increases of 4.7 bushels of corn, 1.5 bushels of soybeans, 1.6 bushels of wheat, and 490 pounds of mixed hay per acre, valued at $25.40, up to the present time. (Compare plots 13 and 14).

Lime and manure together have produced average increases of 21.4 bushels of corn, 4.0 bushels of soybeans, 3.8 bushels of wheat, and 763 pounds of mixed hay per acre, amounting to $17.81 for the rotation. (Compare plots 14 and 16).

$6.84 WELL SPENT

Phosphate and potash on the corn and complete fertilizer on the wheat have produced average increases of 19.7 bushels of corn, 4.7 bushels of soybeans, 10.3 bushels of wheat, and 1,305 pounds of mixed hay per acre, amounting to $25.09 at a total cost of $6.84 for the fertilizer. (Compare plots 12 and 14).

TOP-DRESSING WHEAT WITH NITROGEN

Beginning with 1928, the wheat on the west ends of plots 4, 6, 12 and 20 of the General Fertility Test has been given a spring top-dressing of 15 pounds of nitrogen per acre. The average results for the five years are shown in the following table:

TABLE II.--RESULTS OF TOP-DRESSING WHEAT WITH NITROGEN IN SPRING

Plot No.	Treatment	Bushels wheat per acre 1928-1932	Bushels increase due to spring top-dressin
4 east end	2-12-6 in fall	14.8	
4 west end	2-12-6 in fall + 58# N in spring	20.0	5.2
6 east end	2-12-6 in fall	16.5	
6 west end	2-12-6 in fall + 15# N in spring	22.2	5.7
12 east end	2-12-6 in fall	12.3	
12 west end	2-12-6 in fall + 15# N in spring	17.9	5.6
20 east end	2-12-6 in fall	17.9	
20 west end	2-12-6 in fall + 15# N in spring	23.6	5.7

Top-dressing the wheat with 15 pounds of nitrogen per acre in April ha increased the yields by 5.2 to 5.7 bushels per acre. This increase ha averaged one bushel of wheat for each 2.7 pounds of nitrogen applied. Wit nitrogen at 7.5 cents per pound, the increase in yield has been secured a a cost of 20 1/4 cents per bushel.

COMPARISON OF DIFFERENT PHOSPHATES

The object of this experiment is to determine the relative values o superphosphate, rock phosphate, bone meal, and basic slag as phosphatic fertilizers. Superphosphate and rock phosphate are also compared in severa different proportions with and without lime, manure, nitrogen and potas fertilizers.

This field was laid out and tile drained in the summer of 1915. Th crop rotation is corn, wheat and clover with all produce removed, excep second growth clover.

The treatments shown in the second column of the table are as follows L = ground limestone; M = manure; St.B. = steamed bone meal; BS = basi slag; SP = superphosphate; RP = rock phosphate; N = 12 pounds nitrogen K = 50 pounds potash.

Ground limestone was applied at the rate of 4 tons per acre in 1915 an an additional 2 tons in 1931.

Manure was applied at the rate of 6 tons per acre for corn in the firs round of the rotation and since then in amounts equal to the produce remove except wheat grain. The phosphates are applied at the rates shown in th third column in Table III. The rock phosphate is plowed under for corn an the other phosphates, and the nitrogen and potash are broadcast and harrowed in before planting. The following table shows the results to date c treatments begun in 1916.

TABLE III.--Results of Phosphate Experiment.

	Av.LM checks		40.0	9.4	1855	30.94			

1. Plot 13 was manured on Series B in 1916 and Series C in 1917.
2. Plots 17, 18, 20 and 21 receive 12 pounds of nitrogen and 50 pounds of potash per acre per rotation, all on the corn.
3. Applied in 1916 and again in 1925.

NOTE.--In computing the financial results, corn has been valued at 40¢, and wheat at 80¢ per bushel and hay at $8.00 per ton. Straw and stover have not been counted. Nitrogen has been charged at 7 1/2¢, phosphoric acid at 6¢ and potash at 6¢ per pound. Rock phosphate (30%) has been charged at $12.00, and ground limestone at $2.50 per ton. Manure has been charged at 50¢ per ton for spreading on the land.

The largest returns have been secured from the combination of ground limestone, manure and medium to heavy applications of superphosphate (plots 5 and 26). The heavy treatment (plot 26) has produced average increases of 27.2 bushels of corn, 10.8 bushels of wheat, and 1,681 pounds of mixed hay per acre over the average of the untreated land. (Compare plot 26 with 33).

In combination with lime and manure, superphosphate has been the most profitable source of phosphorus. (Compare plots 5, 3, 2 and 6). In this comparison, superphosphate, basic slag and steamed bone meal have been applied at the rate of 48 pounds and rock phosphate at 192 pounds of phosphoric acid per acre with manure for each corn crop.

On limed land, superphosphate has been more efficient than rock phosphate in all cases, whether used in large or small amounts, and with or without manure or nitrogen and potash (compare plots 5, 11, 17, 23, 26 and 29 with plots 6, 12, 18, 24, 27 and 30).

On manured land without lime, rock phosphate has been slightly more profitable than superphosphate (compare plots 8 and 9).

Without lime, rock phosphate has produced larger returns than the combination of lime and superphosphate. In both cases, however, the crop yields have been too low to be profitable.

VARIETY TESTS OF FARM CROPS

The selection of hardy, high-yielding varieties of the crops grown in any section is very important. To determine those best adapted for this part of the state, the most promising varieties of several crops have been compared each year for a number of years. Each variety has been harvested separately and the yields determined by weight. The land on which the variety tests are carried has been kept in a good state of fertility by uniform applications of fertilizer on wheat, and manure on each corn crop.

Table IV.--Results of Crop Variety Tests, 1922--1932

PASTURE EXPERIMENTS

The improvement of pasture land has a very definite place in the agricultural program for southern Indiana. Large areas of this section are better adapted to pasture purposes than to its present use. There is a considerable area of pasture land that is not producing in a satisfactory way. The development of better pastures will make possible the expansion of the livestock industry from both the beef cattle and the dairy cattle point of view.

Several years ago a series of pasture plots was laid out in one section of the old pasture, and the results of soil treatment are given in the following table.

Grass mixtures including timothy, red top, Kentucky blue grass, orchard grass, alsike clover, sweet clover, alfalfa and lespedeza were seeded on the p plots in April, 1924. The first 2 years' growth was largely alsike clover, timothy and red top with scattered clumps of orchard grass, sweet clover and alfalfa.

BETTER PASTURES

After 9 years blue grass and red top persist along with some timothy on the fertilized plots. Blue grass is much better on the limed and phosphated areas than on the unlimed. Most of the lespedeza, both Korean and common, seemed to have disappeared in the extreme drouth of 1930 but is slowly coming back. Hop clover, a member of the clover family, gradually came into the mixtures. This early growing legume seems to have some real worth for rolling pasture land of this type.

For new pasture seedings a mixture of timothy, red top, blue grass, alsike clover and lespedeza is recommended for rolling limestone land. On sour thin land, a mixture of lespedeza and red top seems best.

Table V.--Results of Pasture Experiment, 1924-1931

Plot No.	Treatment per Acre*	Green forage, pounds per acre 1924	Green forage, increase over untreated	1925	Cured forage, pounds per acre average 1926-32	Cured forage, increase over untreated
1	Manure	5445	1512	Due to dry weather growth was small in 1925 and nothing was harvested	1381	488
2	500 lb. 2-12-6	16940	13007		2162	1269
3	500 lb. 0-12-6	13613	9680		1564	671

10	Lime, manure	13613	9860		1649	756

* Treatments applied at seeding time in April, 1923, and fertilizer repeated in fall of 1929. Plots 2 and 9 receive top-dressings of 100 pounds of nitrate of soda per acre each spring.

ROTATION EXPERIMENT

A comparison of clover, alfalfa, sweet clover, Korean lespedeza and timothy in rotation with corn and wheat is being made on 17 quarter acre plots.

The effect of these crops on succeeding grain crops, their adaptation and dependability as one year rotation crops and their productive capacity are being studied.

All wheat receives 300 pounds per acre of 2-12-6 fertilizer and corn 100 pounds of 0-12-6 in the row. Manure equal to the total weight of produce (except wheat grain) in the previous round of the rotation is divided between corn and wheat.

The rotations under comparison are:

1. Corn, wheat, timothy (hay)
2. Corn, wheat, clover (hay)
3. Corn, wheat, alfalfa (hay)
4. Corn, wheat, sweet clover (seed)
5. Corn, wheat, (sweet clover intercrop)
6. Corn, wheat, Korean lespedeza (hay and seed).

HORTICULTURAL WORK

The Horticultural Department, Professor L. Greene, Chief and Professor C. L. Burkholder, Assistant Chief , is carrying on numerous projects of interest to fruit growers of the State.

The large planting of promising plum and prune varieties will produce the first fruits this year. Practically all of the commercial acreage of pears in southern Indiana has been destroyed by blight. The work in the three year old pear orchard may bring new information of special value at this time. Other work includes a study of various types of spray schedules and their relation to fruit and foliage injury and residue, storage studies, apple washing costs and comparison of various washing materials, stationary vs. portable spraying, peach and apple variety tests and a half acre farm garden.

USE OF ICE IN AN INSULATED COOL AIR APPLE STORAGE

MARKETING PERIOD LENGTHENED BY ICE

The data on this project dealing with the use of ice during the early fall storage period of Grimes and Jonathan has been carried on since 1925 by the Dep'ts of Horticultural and Agricultural Engineering. A complete report covering the work up to 1933 will be published in a few weeks and those interested should write the Purdue Agricultural Experiment Station for a copy of this publication. Circulating air over large blocks of ice reduced the temperature in the storage from 10° F. to 16° F. - below the temperature of a similar room cooled by ventilation during August and September. When the air was circulated through cracked ice and salt the temperature in the insulated room was 18° F. to 22° F. lower than that of a similar but uninsulated room adjoining. The seasonal cost of icing and operating the iced room varied from 16 to 26.6 cents per bushel with an average of 20.8 per bushel for the six years covered by this report. These are just a few of the interesting and valuable facts to be found in this new bulletin.

APPLE WASHING

Soon after a United States tolerance was placed on arsenic on fruit a commercial apple washer was installed at the farm. A great many tests have been conducted during the past two seasons with various cleaning materials. In 1931 the cost of acid, labor, power and 15 per cent depreciation on the original cost of the washer amounted to 1.05 cents per bushel on the 16,000 crates of fruit run through the washer. In 1932 only 7,600 crates of fruit were run through the washer at a cost of 1.5 cents per box. During the two seasons that this type of washing equipment has been used the average removal of arsenic has been from 60 to 70 per cent of the amount present when the fruit started through the machine. The percentage removal of lead residue has been about the same. However, there is usually three or more times as much lead residue present per pound of fruit as of arsenic. The use of several soap emulsifiers with the 2 per cent by volume hydrochloric acid in 1932 failed to increase the percentage of removal over 2 per cent while some of the emulsifiers tried did not increase the percentage removal over acid alone.

SANITARY MEASURES IN CODLING MOTH CONTROL

SANITATION COUNTS IN CODLING MOTH CONTROL

Up until the day of the meeting the packing shed was kept carefully closed and screened so that none of the moths of the over-wintering codling moth could get into the orchard. All of the orchard crates and bushel baskets that were left over from the 1932 harvest were stored in the basement of this building. The areas in the orchard which have shown the heaviest codling moth infestation in the past have been banded and the trees scraped to encourage pupation of the codling moth larva in the treated bands which destroy them soon after they spin up. Mr. Marshall, in charge of the entomology field station on the farm, has estimated that it costs 11.6 cents to kill 100 codling moth larva by spraying and 1.78 cents per 100 to destroy them by the use of self working bands. Of course the bands cannot be depended upon alone but where codling moths are a serious problem or where they are becoming more numerous neither method should be neglected in carrying out an effective control program.

PLUM AND PRUNE VARIETY TESTS

There are about thirty varieties included in this planting. The trees are located along the west edge of the apple orchard, and nearly directly west of the large machinery shed. Most of the older trees had a very nice bloom in the spring of 1933, and many of the varieties have set enough fruit to give some advance idea of their possible production in this part of the state. It is of special interest to note that all of the varieties remaining in this plot have not been troubled by the low winter temperatures which have destroyed the fruit buds of peaches in this area for the past two years.

PEAR BLIGHT AND VARIETY TEST PLOT

All of the trees in this block are on blight resistant roots. The trunks are also of the Old Home variety, which is partially blight resistant. Last spring these trees had completed two growing seasons in the field, and the scaffold branches were budded to the varieties selected for study. A period of cold, windy weather followed and many of the buds did not set. The branches which have not been worked over at the present time will be budded this fall.

SOIL MANAGEMENT

Up until about five years ago the north half of the apple orchard was kept in grass while the south half was cultivated and a cover crop planted each fall. The area in the south half of the orchard seemed to be level enough that serious erosion could be avoided, but after a number of years trial it was found that the trees in this area were beginning to stand up on mounds and that the soil between the tree rows was gradually washing away. It was then decided to straw mulch as much of the orchard as possible each year. A bale of straw has been used to the tree and some of the area that was mulched three years ago received a second bale of straw per tree in the spring of 1933. The trees in this south area are beginning to show a better, darker green color and are making a longer terminal growth. The mulch and grass crops sown between the rows has aided in stopping erosion.

FARM GARDEN

A HUNDRED DOLLARS WERE SAVED HERE

One of the most interesting plots on the farm is a half acre of farm garden. This has been laid out with the idea of furnishing a constant supply of vegetables and small fruits for the farm table, beginning with rhubarb, asparagus and early radishes and continuing to furnish a daily and inexpensive supply of food well into the fall months. This half acre has furnished over one hundred dollars worth of food for the farm families during each of the last two years. This plot is also located along the west side of the apple orchard and anyone who has even a small plot to devote to vegetable gardening and small fruits will find it well worthwhile to visit the garden.

LIVESTOCK

The livestock work on the farm has been continued on the same basis as last year, with the cooperation of Professor F. G. King, Chief, and Professor Claude Harper, Assistant Chief of the Department of Animal Husbandry. The lamb production test has been carried on using a lot of type C merino ewes headed by a merino buck, and the following lots each headed by a southdown buck - merino ewes; western ewes and native ewes. Records are being kept of the feed consumption so that costs, gains, profits and effect on wool production can be determined.

The herd of young cattle is developing nicely. These animals will be the basis for studying the milking and beefing qualities of this strain of Shorthorn cattle. This project is carried on in cooperation with the Bureau of Animal Industry, U. S. Department of Agriculture, and it is hoped that much valuable data will be obtained which will be of interest to all cattle breeders. Records and observations will be made regularly on these animals so that the dual qualities of the progeny may be accurately measured.

POULTRY

A consistent effort is being made to develop one of the finest flocks of Barred Plymouth Rocks in the country. In this work Mr. S. M. Walford of the Department of Poultry Husbandry advises regarding tthe management and assists in the development of a constructive breeding program.

A uniform intermingling of the several Indiana and imported blood lines in the flock of 750 pullets and hens is beginning to show results in a more uniform, high egg production.

By pedigree breeding and wing banding, the progeny of outstanding females is definitely indentified.

1933	....	....	774,000	....

* Indiana Crops and Livestock, 1933. Department of Agricultural Statistics.

NINETEENTH ANNUAL REPORT OF THE CREAMERY LICENSE DIVISION

T. H. Binney

Indiana Dairy Statistics

In spite of economic conditions, Indiana retained its position among the leading dairy states of the nation in the production and manufacture of dairy products during 1932. Indiana's rank among the states for 1932 in the manufacture of the principal dairy products is as follows:

Product	Rank
Butter	8th
Pressed Cheese	4th
Cottage Cheese	9th
Sweetened Condensed Milk	8th
Unsweetened Condensed Milk	1st
Evaporated Milk	10th
Ice Cream	11th

As shown in the following table, manufactured dairy products did not follow the general trend of percentage changes in 1932 when compared with 1931.

PERCENTAGE CHANGE OF PRINCIPAL MANUFACTURED DAIRY PRODUCTS IN 1932 FROM 1931

PRODUCT	Unit	Percentage change 1931 to 1932	
		*United States	Indiana Licensed Plants
Creamery Butter	Pounds	+ 1.6	+11.0
Cheese	Pounds	— 1.7	+ 3.8
Condensed Milk	Pounds	—17.5	—19.2
Evaporated Milk	Pounds	+ 9.9	— 3.2
Ice Cream	Gallons	—25.8	— 7.6

*Dairy Situation, September 19, 1933. U. S. D. A. Bureau of Agricultural Economics.

At the time of applying for the renewal of creamery licenses, all creameries, milk plants, cheese factories, condenseries, etc., report the amount of butter, milk, cheese, or other dairy products made or sold during the year. With this information, together with figures supplied through a co-operative agreement with the U. S. D. A., Bureau of Agricultural Economics, it is possible to compile reliable statistics concerning the total production of licensed dairy manufacturing plants.

The following table is a summary of the reports received from licensed plants for the years indicated:

OUTPUT OF LICENSED PLANTS IN INDIANA FOR 1914, 1920, 1926, 1931 AND 1932

	1914	1920	1926	1931	1932
Pounds of Butter	26,636,520	42,577,180	56,091,822	67,991,081	75,506,568
Pounds of Milk	51,067,066	155,950,136	367,074,252	602,079,739	505,210,133
Pounds of Cream	5,421,838	12,224,488	25,800,641	70,230,197	28,833,326
Gallons of Ice Cream	2,035,874	4,132,318	4,604,079	3,932,034	3,653,512
Pounds of Cheese	211,922	233,806	216,548	14,703,669	15,265,027
Pounds of Sweetened Condensed Milk	1,019,400	6,920,592	11,469,103	1,418,904	1,258,553
Pounds of Evaporated Milk	10,106,800	10,265,791	17,280,480	38,521,763	37,301,632
Pounds of Bulk Evaporated Milk	2,450,988	5,977,716	7,847,662	32,886,766	27,518,303

By comparing the figures for 1932 with those for 1931 in the above table, it will be noted that butter, milk and cheese show an increase while the remaining products show a decrease. The increase in the amount of butter made is 7,515,487 pounds, or 11 per cent. A total of 505,210,133 pounds of milk and 28,833,326 pounds of sweet cream were sold in licensed plants during the past year. This represents an increase of 0.6 per cent of milk and a decrease of 143.5 per cent of cream in 1932 as compared with 1931. The amount of ice cream manufactured during the past year shows a decrease of 278,522 gallons, or 7.6 per cent. Cheese production increased 561,358 pounds, or 3.8 per cent. Sweetened condensed milk decreased 160,351 pounds, or 12.7 per cent; evaporated milk (case goods) decreased 1,220,131 pounds, or 3.2 per cent, and bulk evaporated milk decreased 5,368,463 pounds, or 19.1 per cent.

In addition to the above products, dairy plants of the state manufactured 13,888,634 pounds of condensed skim milk; 1,214,650 pounds of evaporated skim milk; 3,738,624 pounds of concentrated skim milk (for animal feed); 6,741,032 pounds of condensed or evaporated buttermilk; 4,650,823 pounds of dried or powdered skim milk, and 1,911,990 pounds of dried or powdered buttermilk.

An estimate of the total amount of dairy products manufactured in the state may be secured by using the above statistics and estimating the amount of dairy products manufactured and sold in the plants which are not licensed. A large number of ice cream plants and market milk plants buy milk on a gallon or weight basis rather than on a butterfat basis and do not come under the jurisdiction of the Creamery License Division.

AMOUNT OF BUTTER, MILK, ICE CREAM, CONDENSED MILK AND CHEESE
ESTIMATED AS PRODUCED IN INDIANA DURING 1932

Pounds of Creamery Butter	75,506,568
Pounds of Dairy Butter	10,305,055
Pounds of Milk Consumed	1,649,080,903
Gallons of Ice Cream	9,072,953
Pounds of Condensed and Evaporated Milk	66,078,488
Pounds of Cheese	15,265,027
Pounds of Cottage Cheese	2,937,193

By taking the amount of milk used in the manufacture of each of the various dairy products, the total milk production of the state may be calculated. In making this calculation, it has been necessary to estimate the amount of milk and cream consumed direct, the amount of dairy butter made, the amount of milk fed to calves, and the amount of milk lost on farms and in factories.

TOTAL (ESTIMATED) MILK PRODUCTION

Creamery Butter Used	1,585,637,928	pounds
Dairy Butter Used	216,406,155	pounds
Milk Consumed Direct	1,649,080,903	pounds
Ice Cream Used	124,753,106	pounds
Cheese Used	152,650,270	pounds
Condensed Milk Used	165,196,220	pounds
Milk Fed to Calves	110,181,400	pounds
Milk Shipped Out of State	272,750,432	pounds
Losses on Farms and in Factories	128,299,692	pounds
Total	4,404,956,106	pounds
Milk Shipped in	202,537,975	pounds
Total Milk Production in Indiana	4,202,419,131	pounds

Creamery Licenses

Every factory and station where milk or cream is bought on a butterfat basis is required to have a creamery license. A creamery license is valid for one year, providing that the Law or the Rules and Regulations under which the license was granted are not violated. In case of a violation, a creamery license may be revoked by the Purdue University Agricultural Experiment Station.

During the past year 1,752 creamery licenses were issued. This is a decrease of 77 from the previous year's total of 1,829. Plant licenses show a gain of 17 in number, while the number of station licenses show a decrease of 94.

The following table is a summary of the number and kinds of plants issued creamery licenses during the year ending March 31, 1933, and for previous years, as indicated.

CREAMERY LICENSES ISSUED FROM 1926-1932, INCLUSIVE

PLANTS AND STATIONS	NUMBER AND YEAR						
	1926	1927	1928	1929	1930	1931	1932
Butter	64	58	56	58	56	58	57
Milk	91	108	129	141	162	147	162
Ice Cream	17	15	11	16	18	16	12
Cheese	3	9	18	17	18	19	18
Condensed Milk	7	8	8	9	8	10	10
Butter and Milk	33	43	39	33	36	46	54
Butter and Ice Cream	12	14	17	13	10	13	9
Butter and Condensed Milk	1	1	0	0	0	0	1
Butter and Cheese	0	0	3	2	1	2	3
Butter, Milk, and Ice Cream	13	16	13	15	20	17	23
Butter, Milk and Condensed Milk	4	4	5	5	7	6	2
Butter, Milk, Ice Cream and Condensed Milk	4	6	7	7	6	6	7
Butter, Milk, Ice Cream and Cheese	0	0	0	0	0	1	1
Butter, Milk, Cheese and Condensed Milk	0	0	0	1	0	0	1
Milk and Ice Cream	19	20	24	18	19	26	25
Milk and Condensed Milk	3	3	2	5	4	5	4
Milk, Ice Cream and Condensed Milk	1	2	2	3	2	0	0
Milk, Ice Cream and Cheese	0	0	0	1	1	0	0
Total number of Plants	272	307	334	344	369	372	389
Stations	1,631	1,653	1,614	1,588	1,524	1,457	1,363
Total Licenses Issued	1,903	1,960	1,948	1,932	1,893	1,829	1,752

The following table shows the number of plants which reported each of the five major products handled in licensed plants for the years indicated:

PRODUCT	NUMBER OF PLANTS REPORTING						
	1926	1927	1928	1929	1930	1931	1932
Butter	131	142	140	134	136	149	158
Milk	168	202	221	229	257	254	279
Ice Cream	66	73	74	73	76	79	77
Cheese	3	9	21	21	20	22	22
Condensed Milk	20	24	24	30	28	31	25

Testers' Licenses and Examinations

Before obtaining a license to test milk or cream, testers must demonstrate their ability to make reliable tests by passing an examination consisting of both written and laboratory work. The written examination covers general information of testing procedure and consists of twenty questions taken from Circular 41 issued by the Purdue University Agricultural Experiment Station. In the laboratory, candidates must demonstrate their ability to prepare samples for testing, weigh out accurate samples of cream, measure accurate samples of milk, make correct readings of tests and show their general knowledge of the operation of the Babcock test.

Three hundred and forty-two candidates appeared for the tester's examination during the past year. This is the smallest number of candidates to take the examination in any year since the Creamery and Testers' License Law was passed. Out of this number twenty failed to receive a passing grade; fourteen of the failures were due to unsatisfactory written work, one was due to laboratory work and five were due to both written and laboratory work.

Twenty-one hundred and nine testers' licenses were issued during the past year, a decrease of two hundred and six from the previous year's total of twenty-three hundred and fifteen.

The following table shows the number of candidates examined and testers' licenses issued for the year indicated:

NUMBER OF CANDIDATES EXAMINED AND TESTERS' LICENSES ISSUED FOR THE YEARS ENDING MARCH 31, 1920, 1924, 1928, 1932 AND 1933

	1920	1924	1928	1932	1933
Number of Individual Examinations	1,339	850	904	501	342
Number of Failures	226	125	290	33	20
Number of Persons Passing Examination	1,113	725	614	468	322
Number of Testers' Licenses Issued	2,371	2,518	2,661	2,315	2,109

The results of the seventy examinations which were held at the nine examination points in the state are given in the following table:

RESULTS OF TESTERS' EXAMINATIONS, 1932-1933

PLACE OF EXAMINATION	Number of Examinations	Number of Candidates	AVERAGE GRADES (PER CENT)		
			All Candidates	Candidates Passed	Candidates Failed
Lafayette	13	84	82.7	84.8	27.0
Muncie	7	49	83.0	85.8	62.5
Fort Wayne	8	70	84.4	86.0	57.0
New Albany	4	13	79.8	81.2	62.0
Evansville	6	19	84.3	84.3	....
Terre Haute	6	30	82.9	83.9	54.0
Indianapolis	6	38	83.0	83.4	67.0
North Vernon	6	39	83.3	84.9	69.0
Totals	56	342	83.2	84.8	57.1

Glassware Inspection

The first requisite in securing an accurate test of milk or cream is a representative sample. Of equal importance in securing an accurate test is the use of accurate Babcock testing glassware and accurate weights. To assure the dairy industry that their test bottles, milk pipettes, and weights are accurate, they are examined by the Purdue University Agricultural Experiment Station. If they are within the allowable tolerance they are stamped with the letters

"S. G. P.," meaning "Standard Glassware, Purdue." The use of glassware not stamped with the letters "S. G. P." is a violation of Sections 7 and 13 of the Creamery and Testers' License Law and Rule 3 of the Rules and Regulations.

During the past fiscal year 34,079 pieces of Babcock testing glassware were examined by the Glassware Inspector of the Agricultural Experiment Station. In addition, 194 nine-gram weights were inspected and all found to be correct. This is 5,218 pieces of glassware less and 170 nine-gram weights more than were inspected last year.

The following table gives the amount of each kind of glassware inspected, and the number of pieces found to be incorrect:

GLASSWARE INSPECTION

KINDS OF GLASSWARE	Total Number of Pieces	Number Incorrect	Per Cent Incorrect
Cream Test bottles	25,476	61	.239
Milk Test bottles	7,548	0	.000
Milk Pipettes	1,055	0	.000
Summary	34,079	61	.179

Licenses Revoked and Prosecutions

One of the duties of the Creamery License Division is to insure accurate tests and weights of milk and cream to both the producer and manufacturer. This is accomplished through inspectors who inspect cream and milk stations, and factories, to determine the accuracy of tests, weights, and records of milk and cream purchased. Whenever an operator is found manipulating tests, weights, or records, either intentionally or unintentionally, he is first warned to discontinue such practice. If such violations continue, the inspectors obtain evidence which is placed before the State Creamery Examining Board. The operator against whom the evidence is obtained is requested to appear before the Board to show cause why the license should not be revoked. After a careful consideration of all the evidence presented, the Board recommends to the Purdue University Agricultural Experiment Station the action to be taken.

During the past year the following testers' licenses were revoked in accordance with the recommendation of the Examining Board:

Mr. Russel Moore, Indianapolis, Marion County, Indiana, tester for Model Creamery, Indianapolis, Indiana.

Mr. J. M. Hopewell, Farmersburg, Vigo County, Indiana, independent buyer for Johnson Butter Company, Terre Haute, Indiana.

Mr. James L. Conder, Jasonville, Greene County, Indiana, tester for Highland Creamery Company, Terre Haute, Indiana.

Mrs. Mary R. Smith, Fountain City, Wayne County, Indiana, tester for Wayne County Produce Association, Richmond, Indiana.

Mr. Earl Daugherty, Hagerstown, Wayne County, Indiana, tester for Red 73 Creamery Company, Union City, Indiana.

One prosecution was made during the year. An operator was found guilty of testing without a license and paid the costs of prosecution which amounted to $12.00.

LIBRARY
UNIVERSITY OF ARIZONA

Circular No. 199 October, 1933

INSPECTION OF AGRICULTURAL SEEDS

Buckhorn seeds are often found in improperly cleaned clover, timothy and lawn grass seed.

UNIVERSITY OF ARIZONA LIBRARY

Agricultural Experiment Station
Purdue University
Lafayette, Indiana

This circular is a report of the agricultural seed inspection work for the year ending June 30, 1933. The inspectors visited seed dealers in all sections of the state and collected 1,043 official seed samples. In addition to these, 2,852 free test samples of seed were tested during the year.

In accordance with the ruling of the State Seed Commissioner, wholesale seedsmen are required to attach at least one state label to each package of seed delivered to the retail seedsmen, who are then required to attach sufficient additional labels to cover the net weight of the package.

Since it is impossible to test all seed promptly during the rush season, directions are given for making germination tests at home.

Shipments of seed seriously misbranded were withdrawn from sale until dealers relabeled such seed correctly.

Proper use of this publication will enable purchasers to discriminate between seedsmen who handle good seed and those who handle poor seed. Before buying seed, farmers are urged to examine Table 7, "Summary of Seed Inspection."

Due to lack of funds, the table giving the analyses of individual samples is omitted from the report this year. It is the intention to resume publication of this table in future reports as soon as funds are available.

INSPECTION OF AGRICULTURAL SEEDS

H. R. Kraybill, *State Seed Commissioner*

O. S. Roberts, P. B. Curtis, Regina B. Schulte*, Pauline Balbach

The Indiana Seed Law is essentially a correct labeling law. The law does not prevent the sale of poor seed. It merely requires that definite information be placed on the label in order that the purchaser may decide for himself whether he wishes to use good seed or poor seed. In order that the necessary information may be available the law requires that the seed be labeled with official Indiana State Labels showing the minimum percentage of purity and of germination and the maximum number of each of the noxious weed seeds per pound. The purpose of the law is to give the purchaser sufficient information to enable him to buy good seed and also to protect the honest and reliable seed dealer and farmer from the practices of the unscrupulous, dishonest and careless seedsman.

This circular contains the results of the inspection of agricultural seeds for the period from July 1, 1932, to June 30, 1933. The inspectors visited the seed dealers in all sections of the state and collected 1,043 official samples of seed. Complete analyses of these samples were made and reports were sent to the retail dealers as well as to the distributors of the seed. In addition 2,852 free test samples and 22 Custom House samples were analyzed. The testing of these samples entailed the making of 2,656 purity tests, 12,748 germination tests, 105 examinations and 224 identifications.

Responsibilities of the Wholesale Seedsman

The wholesale seedsman is required to attach at least one Indiana State Label to each package of seed delivered to the retail seedsman.

Responsibilities of the Retail Seedsman

The retail seedsman is required to attach sufficient state labels properly filled out to each package of seed to cover the total weight of the seed before the seed is offered or exposed for sale. These labels can be chosen of such denominations of weight so that they may be removed and attached to a portion of the seed which may be sold from the original package. It should be remembered that every package of seed of one pound or more when sold for seeding purposes must have attached to it sufficient state labels properly filled out to cover the total weight of the package. It should also be remembered that it is just as much a violation of the state law to offer or expose seed for sale for seeding purposes without tagging to full weight as it is to sell the same without tagging.

Responsibilities of the Purchaser

The purchaser should examine the official label carefully before purchasing seed and ascertain whether the seed is of the quality he desires. He should insist that all seed which he purchases be tagged properly with official state labels. Attention should be paid to the date of germination on the seed tag. If the germination test was made more than six months before, in many cases it will be well to insist upon a more recent germination test. Table 7 gives the standing of the distributors as determined by the 1933 inspection. A study of this table will enable you to determine whether or not the seed which they sold met their guarantee. The seed law is designed to offer you protection but it will not give you that protection unless you make use of the opportunity which the law provides for you.

---

* In cooperation with the Seed Laboratory, Bureau of Plant Industry, U. S. D. A.

Farmers' Exemption

A farmer is exempt from the provisions of the seed law when the seed is grown, sold, and delivered by that farmer on his own premises to the purchaser himself. If, however, the seed is advertised for sale by the public press, circular or catalogue, or if the seed is delivered by a common carrier, the farmer is considered as a vendor and must comply with the provisions of the act. **Seed taken to community sales for sale must be labeled in accordance with the law.**

Free Testing of Seeds

During the past year 2,852 samples of seed were tested free of charge for farmers and seedsmen. The privilege of having these tests made is one of much value to the farmer and the smaller seed dealers who do not have facilities for testing seeds. Not all of the tests requested can be made promptly during the busy season from January to March. For that reason it is important that you send your samples in as early as possible, preferably from September to December.

Satisfactory tests may be made of the larger field seeds at home, leaving the laboratory facilities of the Experiment Station available for the grasses and clovers which are more difficult to analyze.

Directions for Making Your Own Germination Tests

The seed to be germinated should be mixed thoroughly and the required number of seeds (100 seeds of grains and 200 of clovers and other small seeds) counted out just as they come.

The plate germinator is satisfactory and very simple to operate. Place the seeds to be germinated between two thicknesses of folded blotting paper or cloth (heavy grade of muslin or canton flannel). This should be moistened and placed between ordinary tin or porcelain plates and kept in a warm room where the range in temperature is from approximately 85 degrees during the day to 65 degrees at night. Select a place for the test not too near a window, stove or register.

The time required for germination tests differs with different kinds of seed. Under favorable conditions grass and clover seeds begin to sprout in three or four days. Continue your tests ten days or two weeks.

Examine your tests every two days, making a record of the number of seeds that have sprouted. Also keep the blotting paper or cloth sufficiently moist. The number of seeds which germinate out of the 100 seeds will give the percentage of germination.

Directions for Taking of Samples

1. The minimum weight of seed forwarded for test should be approximately:
   - (a) Two ounces (cupful) of grass seed of any kind or of white and alsike clover;
   - (b) Five ounces (cupful) of red and crimson clover, alfalfa, millet, flax or seed of like size;
   - (c) One pound (pint) of cereals or seed of like size.

2. They may be drawn:
   - (a) With seed triers;
   - (b) With long stickers;
   - (c) By hand, taking approximately equal parts of the sample from at least three different places in the sack, including the top and opposite sides as near the bottom as practicable.

3. Samples should be drawn from each bag when there are not more than five bags in the lot, from every fifth bag when there are more than five bags, but never from less than five bags. Each sample so drawn is combined into one composite sample.

Tolerance

Under the most perfect and approved conditions of testing seeds variations will occur in purity and germination tests. For this reason the Association of Official Seed Analysts has adopted tolerances or allowances for purity and germination tests. Samples of seed with a guarantee within the tolerances are not considered to be seriously misbranded under the provisions of the Indiana Seed Law, but seed dealers will be expected to change the guarantee on the unsold portion to correspond to the analysis found by the Seed Commissioner.

Table of Tolerances for Germination Tests

Percentage of Germination	Percentage of Allowable Variation
90 or over	6
80 or over and less than 90	7
70 or over and less than 80	8
60 or over and less than 70	9
50 or over and less than 60	10
40 or over and less than 50	10
30 or over and less than 40	9
20 or over and less than 30	8
10 or over and less than 20	7
0 or over and less than 10	6

Tolerance for Purity Test

In determining the tolerance for purity the sample shall be considered as being made up of two parts: (1) pure seed and (2) everything not pure seed. The tolerance allowed shall be two-tenths of 1 per cent plus 20 per cent of the lesser part. Example: Seed marked 98 per cent pure, the lesser part is 100 minus 98, or 2. Twenty per cent of 2 equals 0.4. Therefore, the tolerance allowed would be 0.2 plus 0.4, or 0.6.

Violation of the Law

It is a violation of the State Seed Law to offer, expose for sale or sell seed without having it tagged to full weight with official labels or to misbrand the seed. During the past year two cases of non-tagging of seed and four cases of misbranding were called to the attention of prosecuting attorneys. Of the six cases three resulted in convictions while three of them have not been reported by the prosecuting attorneys to date.

Filling Out Official Label

Purity

The minimum purity means the percentage of pure seed of the kind and variety given on the official label. Statements of purity, as 97 per cent, including 2 per cent crop seeds, or 95 per cent and 2 per cent crop seeds, will not be permitted. In cases where the seed contains two or more kinds of agricultural seed, each present in excess of 5 per cent, the seed should be labeled with the green colored mixture labels, Style C.

The percentage of purity on the large seeds such as soy beans, corn, wheat, vegetable seeds, etc., must be given on the official label the same as on any other seed.

The filling out of the column "per cent of seed" on the mixture labels can be best explained by an example. For instance, if a mixture is composed of 60 per cent Kentucky Blue Grass with a purity of 80 per cent and 40 per cent of

Red Top with a purity of 90 per cent, the per cent of Blue Grass should be given as 48 per cent, obtained by taking 80 per cent of 60. The Red Top should be given as 36 per cent, obtained by taking 90 per cent of 40.

Germination

There still appears to be some misunderstanding as to the method of stating the percentage of germination on the official label. The term minimum germination means the percentage of sprouts obtained in the prescribed time for the test. If the seed contains hard seeds this percentage should be stated after the term "hard seed" on the official label. In no case should the sum of the percentage of sprouts and of hard seeds be given as percentage of minimum germination.

Distributors should not ship seed until the germination test is completed. The statement "In Test" on the official label does not meet the provisions of the seed law. Further, if there is a demand for the seed the dealer may be tempted to sell the seed before he receives a report on the germination, thus placing himself liable to prosecution.

Noxious Weed Seeds

The number per pound of each of the noxious weed seeds present must be listed on the reverse side of the tag irrespective of the number present. The term "trace" is not permissible. The statement of the noxious weed seeds in terms of per cent or in terms of proportion will not be permitted.

Place Where Grown

The official tag must give the name of the state, territory or foreign country where the seed was grown. Terms such as Domestic, U. S. A., Northwestern, and Central States do not meet the requirements of the law, and seed found so labeled will be immediately removed from sale until the tags have been corrected.

Certified, Verified and Affidavit Seed

Certified seed is seed whose purity, germination, and variety is certified to by some state certifying agency or an agency closely associated with some state office or department. The seed is shipped in sealed sacks with a certified seed tag attached. During the growing season the fields are inspected to ascertain trueness to variety of crop, and after the harvest the seed is tested to determine whether it meets the prescribed standards of the certifying agency. In Indiana the Indiana Corn Growers' Association certifies corn, wheat, oats, lespedeza, and soy beans. The other most commonly certified seed found in the state is Grimm Alfalfa.

Verified-Origin seed is seed whose origin is attested to by certain government approved seed dealers. Seed verification service deals with origin only, meaning Place Where Grown, and gives no guarantee as to the variety, purity or viability of the seed. At the present time red clover and alfalfa are the only seeds verified as to origin. Verified seed is tagged with tags bearing the official verification emblem.

Affidavit Grimm is alfalfa seed for which the grower has made affidavit at to its being Grimm Alfalfa. This affidavit seed is not regulated by either State or Federal Government.

Bargain Seed

A considerable quantity of unclean, weedy, so-called pasture mixtures of low viability has been shipped into the state by certain mail order seedhouses. By means of extensive advertising in leading farm papers many unsuspecting buyers have been influenced in purchasing these dangerous and, in many cases, worthless lots of seed. These mixtures appear to consist of screenings, tailings, and low grade seed mixed together in order to disguise their real quality. The low price attracts the buyers who forget that good seed is not sold below the prevailing market price and that good seed is the cheapest in the end. Most of these cheap seeds lead to poor stands and infestation of the soil with many troublesome weeds.

Summary of 1933 Inspection

A majority of the samples examined during 1933 met their guarantee very closely. Table 1 shows that there has been a marked improvement in the correct labeling of seeds in the last four years. In 1925, 36.4 per cent of the samples were seriously misbranded while in 1933, 19.9 per cent were seriously misbranded. The per cent of samples seriously misbranded increased slightly over that for 1932.

Examination of Table 4 shows clearly that the quality of much of the seed could be improved by more thorough cleaning. Tables 5 and 6 show the percentages of official samples of red clover, alfalfa, sweet clover, alsike clover and timothy which contained some of the various noxious weed seeds. Compared with 1923 there is a decrease in the percentage of samples of alfalfa which contain curled dock, dodder and red sorrel while there is an increase in the percentage of samples of alsike clover and timothy showing buckhorn and common plantain.

Table 1—Progress in Seed Inspection

Year	Number of Samples Examined	Number Seriously Misbranded	Percent Seriously Misbranded
1925	745	271	36.4
1928	969	289	29.6
1929	1,230	403	32.7
1930	1,044	184	17.6
1931	1,122	201	17.9
1932	926	157	17.0
1933	698	139	19.9
